# 0 Preliminaries

## 0.0 Getting Started with R and RStudio

R is divided up into packages. A few of these are loaded every time you run R, but most have to be selected. This way you only have as much of R as you need.

In the Packages tab, check the boxes next to the following packages to load them:

- `mosaic` (a package from Project MOSAIC)
- `Tintle1` (data sets)

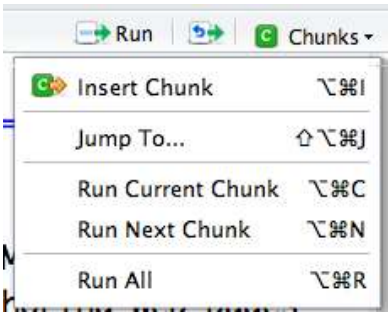
RStudio provides several ways to create documents that include text, R code, R output, graphics, even mathematical notation all in one document. The simplest of these is R Markdown.

To create a new R Markdown document, go to "File", "New", then "R Markdown."

When you do this, a file editing pane will open with a template inserted. If you click on "Knit HTML", RStudio will turn this into an HTML file and display it for you. Give it a try. You will be asked to name your file if you haven't already done so. If you are using the RStudio server in a browser, then your file will live on the server ("in the cloud") rather than on your computer.

If you look at the template file you will see that the file has two kinds of sections. Some of this file is just normal text (with some extra symbols to make things bold, add in headings, etc.) You can get a list of all of these mark up options by selecting the "Mardown Quick Reference" in the question mark menu.

The second type of section is an R code chunk. These are colored differently to make them easier to see. You can insert a new code chunk by selecting "Insert Chunk" from the "Chunks" menu:



(You can also type ```{r} to begin and ``` to end the code chunk if you would rather type.) You can put any R code in these code chunks and the results (text output or graphics) as well as the R code will be displayed in your HTML file.

There are options to do things like (a) run R code without displayng it, (b) run R code without displaying the output, (c) controling size of plots, etc., etc. But for starting out, this is really all you need to know.

R Markdown files are self-contained, meaning they do not have access to things you have done in your console. (This is good, else your document would change based on things not in the file.) This means that you must explicitly load data, and require packages *in the R Markdown file* in order to use them. For this text, this means that most of your R Markdown files will have a chunk near the beginning that includes

```
require(mosaic)  # load the mosaic package
```

Functions in R use the following syntax:

function-syntax

```
functionname(argument1, argument2, ...)
```

The arguments are always *surrounded by (round) parentheses* and *separated by commas*.

Some functions (like `data()`) have no required arguments, but you still need the parentheses.

Most of what we will do in the subsequent chapters makes use of a single R template:

$$\boxed{\phantom{xx}}\left(\boxed{\phantom{x}} \sim \boxed{\phantom{x}}, \texttt{data} = \boxed{\phantom{xxxx}}\right)$$

It is useful if we name the slots in this template:

$$\boxed{\texttt{goal}}\left(\boxed{\texttt{y}} \sim \boxed{\texttt{x}}, \texttt{data} = \boxed{\texttt{mydata}}\right)$$

However, there are some variations on this template:

```
### Simpler version
goal(~x, data = mydata)
### Fancier version:
goal(y ~ x | z, data = mydata)
### Unified version:
goal(formula, data = mydata)
```

To use the template, you just need to know what goes in each slot. This can be determined by asking yourself two questions:

 ©2014

1. What do you want R to do?
   - this determines what function to use (goal).
2. What must R know to do that?
   - this determines the inputs to the function
   - for describing data, must must identify *which data frame* and *which variable(s)*.

Further, if you begin a command and hit the TAB key, R will show you a list of possible ways to complete the command. If you hit TAB after the opening parenthesis of a function, it will show you the list of arguments it expects. The up and down arrows can be used to retrieve past commands.

Additional R funcitonality will be introduced as we go along. The `mosaic` package includes several vignettes with additional information about using the package and using R.

## 0.1 Introduction to the Six-Step Method

### Example P.1: Organ Donations

Now that we've explained a few basics for using R, let's take a look at a data set.

Data sets in R are usually stored as **data frames** in a rectangular arrangement with rows corresponding to **observational units** and columns corresponding to **variables**. A number of data sets are built into R and its packages. The package for our text is `Tintle1` which comes with a number of data sets.

```
require(Tintle1)  # tell R to use the package for our textbook
data(OrganDonor)  # load the OrganDonor dataset
```

If you want a list of all data sets available to you in loaded packages, use `data()` without any arguments. If you want to view the entire data set, just typing the name will show the details in the console.

```
data()  # list all datasets available in loaded packages
OrganDonor  # show entire dataset in console
```

For large data sets, it may be more practical to look at different types of summaries or subsets of the data.

```
head(OrganDonor)       # first six cases of the dataset
```

```
  default choice
1  opt-in  donor
2  opt-in  donor
3  opt-in  donor
4  opt-in  donor
5  opt-in  donor
6  opt-in  donor
```

```
summary(OrganDonor)    # summary of each variable
```

```
   default             choice
 Length:161         Length:161
 Class :character   Class :character
 Mode  :character   Mode  :character
```

```
str(OrganDonor)        # structure of the dataset
```

```
'data.frame': 161 obs. of  2 variables:
 $ default: chr  "opt-in" "opt-in" "opt-in" "opt-in" ...
 $ choice : chr  "donor" "donor" "donor" "donor" ...
```

```
dim(OrganDonor)        # number of rows and columns
```

```
[1] 161   2
```

```
nrow(OrganDonor)       # number of rows
```

```
[1] 161
```

```
ncol(OrganDonor)       # number of columns
```

```
[1] 2
```

Now that we have a general sense of how the data is structured, we can take a more detailed look by using the R template. Let's say we want a count of observational units of each variable. We can tally the number by using the `tally()` function.

```
tally(~choice, data = OrganDonor)
```

```
donor   not
  108    53
```

```
tally(~default, data = OrganDonor)
```

```
neutral  opt-in opt-out
     56      55      50
```

This didn't really show us any more information than the `summary()` from above so instead, let's tally the variables together.

```
tally(~choice + default, data = OrganDonor)
```

```
       default
choice  neutral opt-in opt-out
  donor      44     23      41
  not        12     32       9
```

```
tally(~choice + default, data = OrganDonor, margins = TRUE)
```

```
       default
choice  neutral opt-in opt-out Total
  donor      44     23      41   108
  not        12     32       9    53
  Total      56     55      50   161
```

 ©2014

Notice that the default for `tally()` was to exclude the total counts of each row and column. You could have used either tab completion or search `tally()` in the help section to find `margins` and set `margins=TRUE`. There will be many instances where you will need to change the default settings of a function.

Moreover, we can change the organization of the variables for a slightly different output:

```
tally(choice ~ default, data = OrganDonor)
```

```
       default
choice  neutral opt-in opt-out
  donor      44     23      41
  not        12     32       9
```

```
tally(choice ~ default, data = OrganDonor, format = "percent")
```

```
       default
choice   neutral   opt-in  opt-out
  donor 78.57143 41.81818 82.00000
  not   21.42857 58.18182 18.00000
```

This may be a little confusing now (proportions will be covered in chapter 2) but let's focus more on the the changed organization of the variables in the `tally()` function. This version of tallying calculated the proportions (and percentages) of participants who agreed and did not agree to become organ donors (`choice`) in each of the groups opt-in, opt-out, and neutral (`default`).

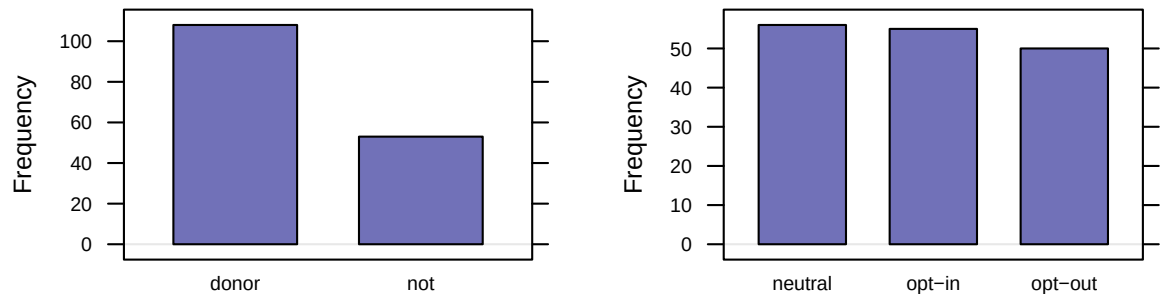
R also has many tools to visualize data.The general syntax for making a graph of one variable in a data frame is

```
plotname(~variable, data = dataName)
```

In other words, there are three pieces of information we must provide to R in order to get the plot we want:

- The kind of plot (`histogram()`, `bargraph()`, `densityplot()`, `bwplot()`, etc.)
- The name of the variable
- The name of the data frame this variable is a part of.

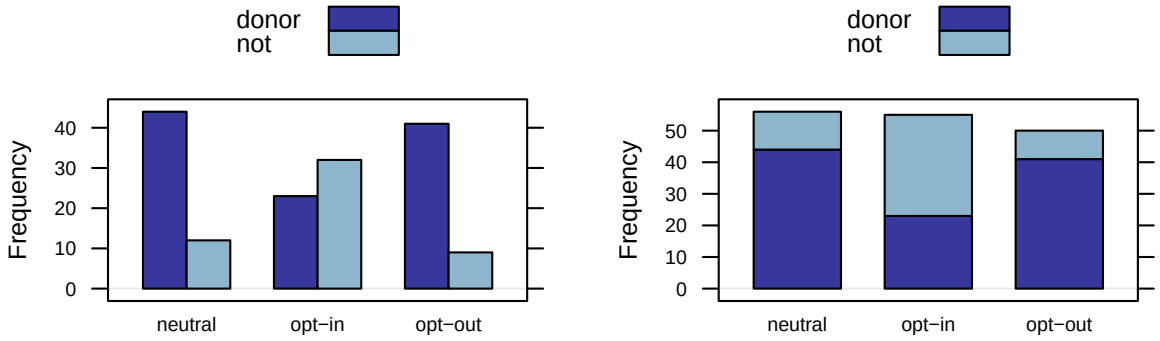
```
bargraph(~choice, data = OrganDonor)
bargraph(~default, data = OrganDonor)
```



Notice that the `bargraph()` uses the frequency, or counts.

In order to graph the variable `default` and show what `choice` each option made, we can utilize the argument `groups=`.

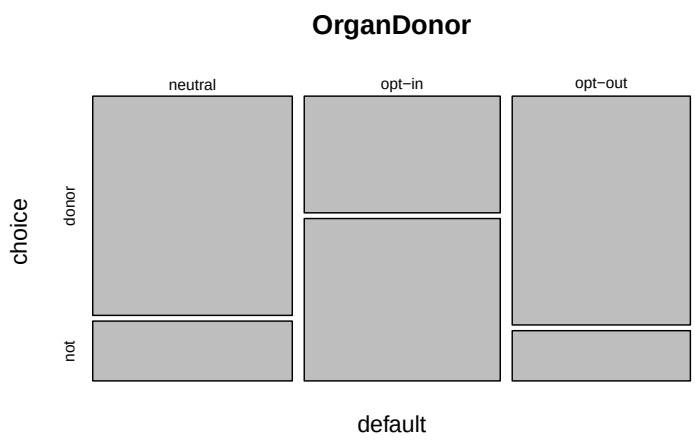
```
bargraph(~default, groups = choice, data = OrganDonor, auto.key = TRUE)
bargraph(~default, groups = choice, data = OrganDonor, auto.key = TRUE, stack = TRUE)
```



Although the bargraph is useful, the y-axis shows counts and not the percentages as in the text. The function `mosiac()` or `mosaicplot()` plots the variables relative to each other, in a way that reveals porportions, or percentages.

```
mosaic(choice ~ default, data = OrganDonor)
mosaicplot(default ~ choice, data = OrganDonor)
```

 ©2014



## 0.2 Exploring Data

### Example P.2: Old Faithful

Everytime you use a new data set, it is beneficial to look at a some key summary statistics.

```
head(OldFaithful1)
```

```
  time
1   55
2   58
3   56
4   50
5   51
6   60
```

```
summary(OldFaithful1)
```

```
      time
 Min.   :42.00
 1st Qu.:60.00
 Median :75.00
 Mean   :71.01
 3rd Qu.:81.00
 Max.   :95.00
```

Another useful graph for examining the **shape**, **center**, and **variability** is the **dotplot**:

```
dotPlot(~Time, data = OldFaithful1)
```

```
Error in eval(expr, envir, enclos):  object 'Time' not found
```

The dots in this plot are a bit small. The defaults for `dotPlot()` may not be the best way to examine a particular data set. We can increase the size of the dots using the `cex` argument. (`cex` stands for "character expansion" and is used to scale up or down the size of plotting characters – in this case the dots.)

```
dotPlot(~Time, data = OldFaithful1, cex = 2)
```

```
Error in eval(expr, envir, enclos):  object 'Time' not found
```

Or we can change the distance between columns of dots

```
dotPlot(~Time, data = OldFaithful1, width = 2)
```

```
Error in eval(expr, envir, enclos):  object 'Time' not found
```

Notice that the dots have been automatically resized when we do this.

The appropriate choice may depend on the intended size and shape of the plot. The plots below are much wider, allowing us to present a finer view of the data. In the second plot, we have also added a more informative label.

FigureP.3

```
dotPlot(~ Time, data = OldFaithful1, width = 1)
```

```
Error in eval(expr, envir, enclos):  object 'Time' not found
```

```
dotPlot(~ Time, data = OldFaithful1, width = 1,
        xlab = "time until next eruption (min)")
```

```
Error in eval(expr, envir, enclos):  object 'Time' not found
```

Similar to the bargraph, we can organize the variables a little differently for the dotplot to graph them in relation to one another.

```
head(OldFaithful2)
```

```
  eruptionType timeBetween
1        short          55
2        short          58
3        short          56
4        short          50
5        short          51
6        short          60
```

```
summary(OldFaithful2)
```

```
 eruptionType        timeBetween
 Length:222         Min.   :42.00
 Class :character   1st Qu.:60.00
 Mode  :character   Median :75.00
                    Mean   :71.01
                    3rd Qu.:81.00
                    Max.   :95.00
```

 ©2014

```
dotPlot(~TimeBetween, groups = EruptionType, data = OldFaithful2, width = 1)
```

```
Error in eval(expr, envir, enclos):  object 'EruptionType' not found
```

The formula for a `lattice` plot can be extended to create multiple panels (sometimes called **facets**) based on a "condition", often given by another variable. This is another way to look at multiple groups simultaneously. The general syntax for this becomes

```
plotname(~variable | condition, data = dataName)
```

```
dotPlot(~TimeBetween | EruptionType, data = OldFaithful2, width = 1, layout = c(1, 2))
```

```
Error in eval(expr, envir, enclos):  object 'EruptionType' not found
```

For more key numerical summaries of the data set, we can use the `favestats()` for "favorite" statistics.

TableP.1

```
favstats(~TimeBetween, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

```
favstats(TimeBetween ~ EruptionType, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

Here are ways to find the mean and the standard deviation separately:

```
mean(~TimeBetween, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

```
sd(~TimeBetween, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

```
mean(TimeBetween ~ EruptionType, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

```
sd(TimeBetween ~ EruptionType, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

```
mean(~TimeBetween | EruptionType, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

```
sd(~TimeBetween | EruptionType, data = OldFaithful2)

Error in eval(expr, envir, enclos):  object 'TimeBetween' not found
```

## 0.3 Exploring random Processes

### Exploration P.3: Cars or Goats

The `mosaic` package has a function `rflip()` that **simulates** coin tosses. We define arguments `n` (the number of flips) and `prob` (the probability of heads).

```
rflip(n = 1, prob = 0.5)

Flipping 1 coin [ Prob(Heads) = 0.5 ] ...

H

Number of Heads: 1 [Proportion Heads: 1]

rflip(n = 5, prob = 0.5)

Flipping 5 coins [ Prob(Heads) = 0.5 ] ...

H H H H H

Number of Heads: 5 [Proportion Heads: 1]
```

Although `rflip()` simulates coin tosses, where the probability of heads should be 0.5, we can also simulate any **random process** by changing the **probability.**

```
rflip(n = 15, prob = 1/3)

Flipping 15 coins [ Prob(Heads) = 0.333333333333333 ] ...

T T T T H T T T H H H H T T H

Number of Heads: 6 [Proportion Heads: 0.4]
```

This is equivalent to the playing 15 games (flips), each game having a 1/3 chance of picking the car (heads).

Further, we can repeat each simulation many times by multiplying it by `do()`. When using `do()`, you should assign the simulation a name by using an arrow (<-) so that you are creating a new data set with all of the repetitions. In this case, we are naming the simulation `GameSims`.

```
# 1000 samples, each of size 200 and proportion 1/3
GameSims <- do(1000) * rflip(n = 10, prob = 1/3)

Loading required package:  parallel
```

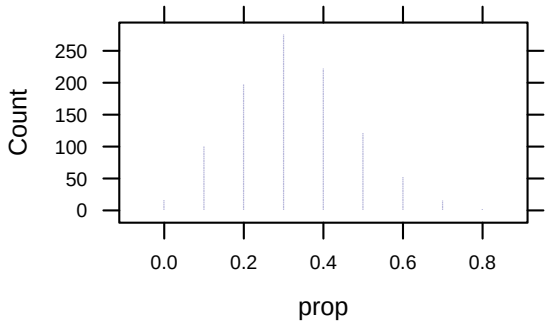
 ©2014

```
head(GameSims)
```

```
  n heads tails prop
1 10     2     8  0.2
2 10     3     7  0.3
3 10     5     5  0.5
4 10     8     2  0.8
5 10     1     9  0.1
6 10     0    10  0.0
```

Now we can create a dotplot of the proportion of wins but note that because of there are so many observations (1000), we will not be able to see the individual dots.

```
dotPlot(~prop, data = GameSims, width = 0.1)
```



## 0.4 Other Visualizations

Several other types of plots can be used in place of dot plots to visualize the distribution of a single quantitative variable. The most familiar of these is the histogram, which replaces the dots of a histogram with rectangles and stacks them up touching each other to form bars. If instead we draw lines connecting the tops of each bar in a histogram (and then erase the bars), the result in a frequency polygon. A density plot is a smoother version of this idea.

Notice that to create these plots (and various numerical summaries), all we have to change is the name of the R function – all of them follow the same general template.

```
    dotPlot(~ prop, data = GameSims, width = 0.1)
  histogram(~ prop, data = GameSims, width = 0.1)
freqpolygon(~ prop, data = GameSims, width = 0.1, ylim=c(0,4))
densityplot(~ prop, data = GameSims)
densityplot(~ prop, data = GameSims, adjust=2)    # "smoother"
densityplot(~ prop, data = GameSims, adjust=0.5)  # less "smooth"
   favstats(~ prop, data = GameSims)
```

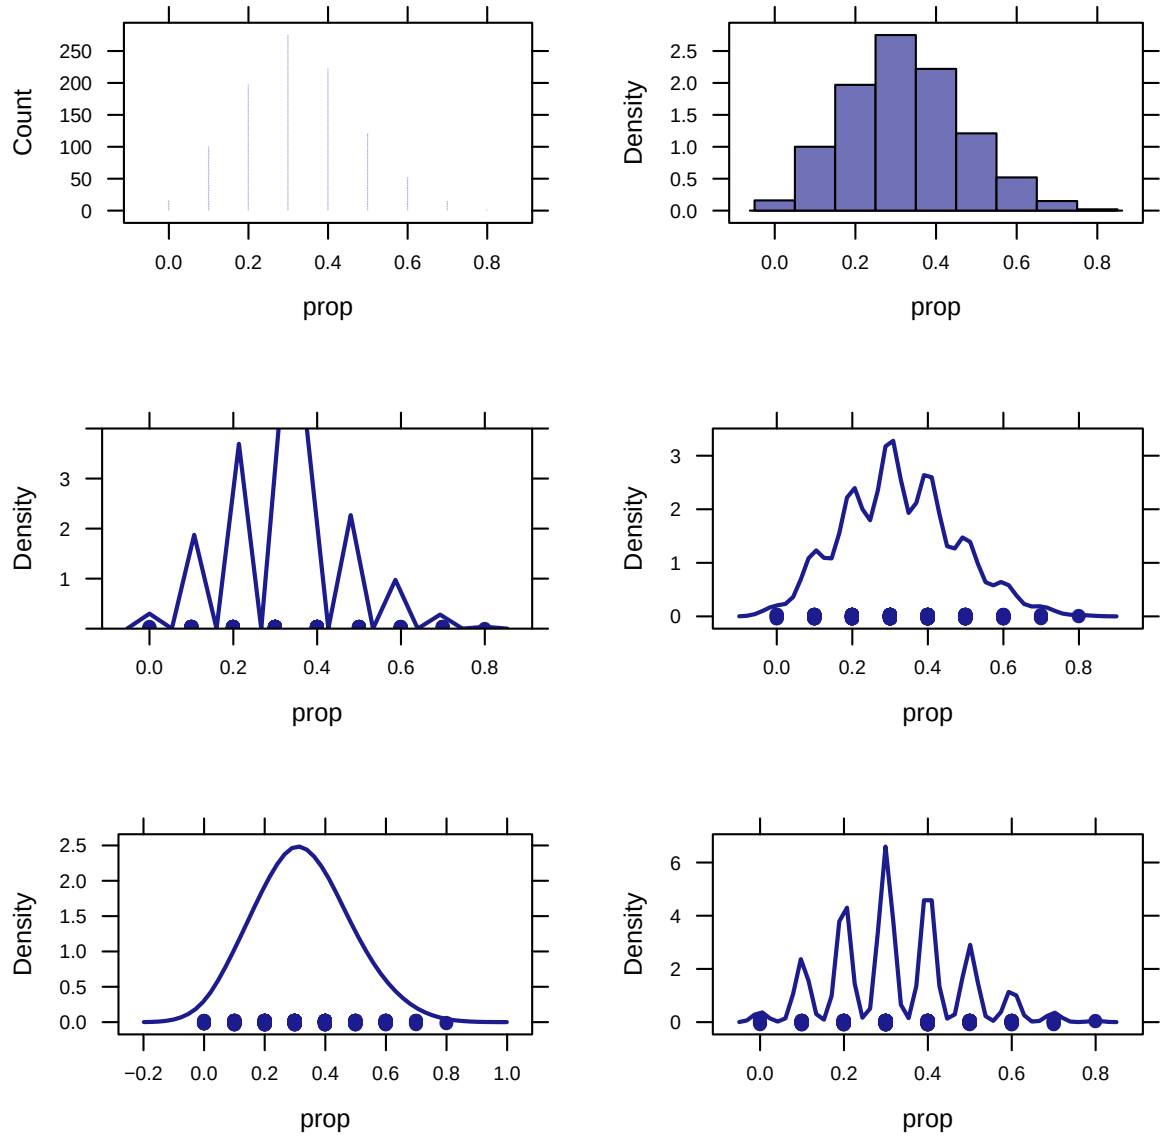
```
 min  Q1 median  Q3 max   mean        sd    n missing
   0 0.2    0.3 0.4 0.8 0.3245 0.1465306 1000       0
```

```
      mean(~ prop, data = GameSims)
```

```
[1] 0.3245
```

```
sd(~ prop, data = GameSims)
```

```
[1] 0.1465306
```



For this data set, a histogram is probably best. This is in part due to the discreteness of the data – there are only 11 possible values for `prop`.

Compared to dot plots, histograms, frequency polygons, and density plots handle a wider range of data sizes. The "sweet spot" for dot plots is around 100–1000 observations. Also, frequency polygons and density plot have the advantage that they can be overlaid.

```
freqpolygon(~TimeBetween, groups = EruptionType, data = OldFaithful2, ylim = c(0, 0.07))
```

```
Error in eval(expr, envir, enclos):  object 'EruptionType' not found
```

```
densityplot(~TimeBetween, groups = EruptionType, data = OldFaithful2)
```

```
Error in eval(expr, envir, enclos):  object 'EruptionType' not found
```

(The current version of `freqpolygon()` is not too clever about choosing the limits for the y-axis – sometimes you need to give it a hand.)

 ©2014

# 1 Significance: How strong is the evidence?

## 1.1 Introduction to Chance Models

### Example 1.1: Can Dolphins Communicate?

The Chance Model

```
rflip(n = 16, prob = 0.5)  # a sequence of 16 coin flips
```

Figure1.2

```
Flipping 16 coins [ Prob(Heads) = 0.5 ] ...

T T T T H T T T T H T H T H T H

Number of Heads: 5 [Proportion Heads: 0.3125]
```

```
rflip(n = 16, prob = 0.5)  # another sequence of 16 coin flips
```

Figure1.3

```
Flipping 16 coins [ Prob(Heads) = 0.5 ] ...

T H T H H T H H T H T H H T H T

Number of Heads: 9 [Proportion Heads: 0.5625]
```

Using and evaluating the coin flip chance model

```
sim <- do(1000) * rflip(16, 0.5)  # 1000 samples, each of size 16 and proportion 0.5
```

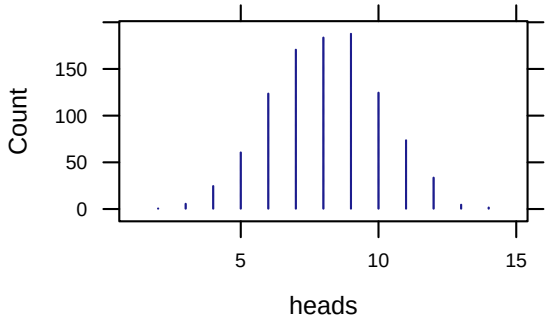
Figure1.4

```
Loading required package:  parallel
```

```
head(sim, 3)
```

```
  n heads tails   prop
1 16     4    12 0.2500
2 16     5    11 0.3125
3 16    11     5 0.6875
```

```
dotPlot(~heads, data = sim, width = 1, cex = 3)
```



Another Doris and Buzz study

```
sim2 <- do(1000) * rflip(28, 0.5)
```

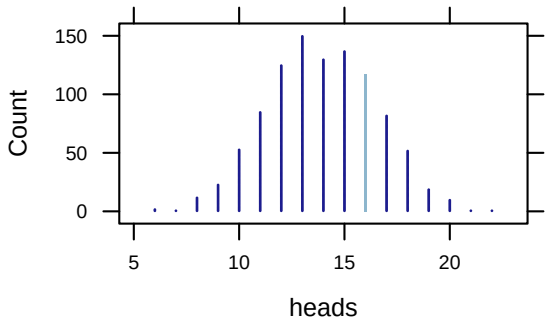
Figure1.6

```
Loading required package:  parallel
```

```
head(sim2, 3)
```

```
  n heads tails   prop
1 28    18    10 0.6429
2 28     9    19 0.3214
3 28    13    15 0.4643
```

```
dotPlot(~heads, data = sim2, width = 1, cex = 3, groups = (heads == 16))
```



©2014

Notice the way we defined `groups` as `(groups = (heads == 16))` in order to differentiate the observations where `heads` equals 16. The == operator means "are equal to". (We could also have used `groups = (heads != 16)` and the colors would be reversed.)

## Exploration 1.1: Can Dogs Understand Human Cues?

### The Chance Model

Exploration1.1.13

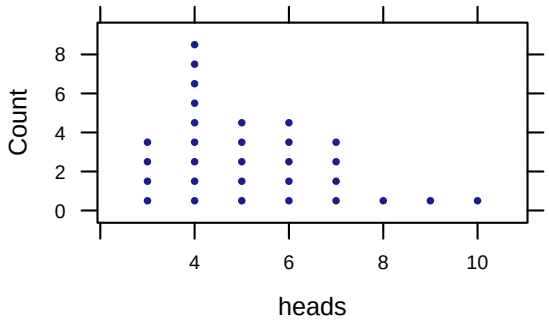
```
sim.harley <- do(1) * rflip(10, 0.5)
sim.harley
```

```
  n heads tails prop
1 10     8     2  0.8
```

```
sim.class <- do(30) * rflip(10, 0.5)
head(sim.class, 3)
```

```
  n heads tails prop
1 10     4     6  0.4
2 10     4     6  0.4
3 10     7     3  0.7
```

```
dotPlot(~heads, data = sim.class, width = 1, cex = 0.5)
```

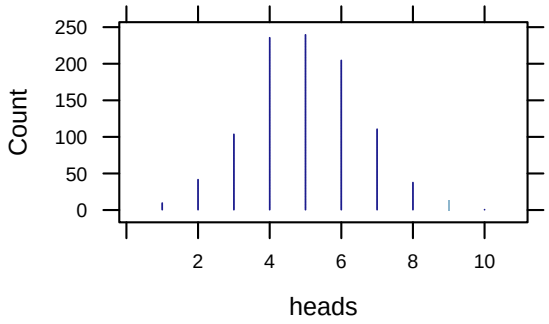


Exploration1.1.14

```
sim.harley2 <- do(1000) * rflip(10, 0.5)
head(sim.harley2, 3)
```

```
  n heads tails prop
1 10     3     7  0.3
2 10     6     4  0.6
3 10     4     6  0.4
```

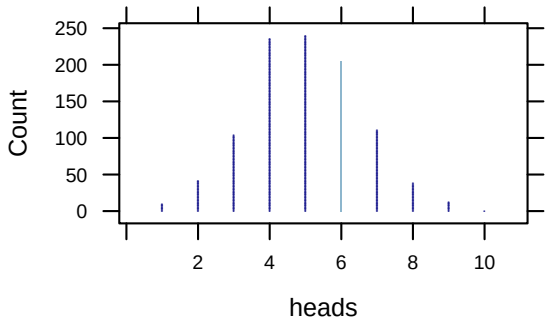
```
dotPlot(~heads, data = sim.harley2, width = 1, cex = 3, groups = (heads == 9))
```



Another Study

```
dotPlot(~heads, data = sim.harley2, width = 1, cex = 3, groups = (heads == 6))
```

Exploration1.1.23



## 1.2 Measuring the Strength of Evidence

### Example 1.2: Rock Paper Scissors

1. $H_0$: $\pi = 1/3$
   $H_a$: $\pi < 1/3$
   Test statistic: $\hat{p} = 0.167$ (the sample proportion of $1/6$)
2. We simulate a world in which $\pi = 1/3$:

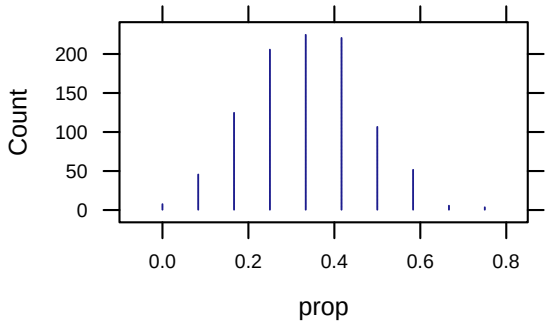
```
sim.sci <- do(1000) * rflip(12, 1/3)
head(sim.sci, 3)

  n heads tails   prop
1 12     7     5 0.5833
2 12     4     8 0.3333
3 12     3     9 0.2500

dotPlot(~prop, data = sim.sci, width = 1/12, cex = 3)
```

Figure1.7

 ©2014



3. Strength of evidence:

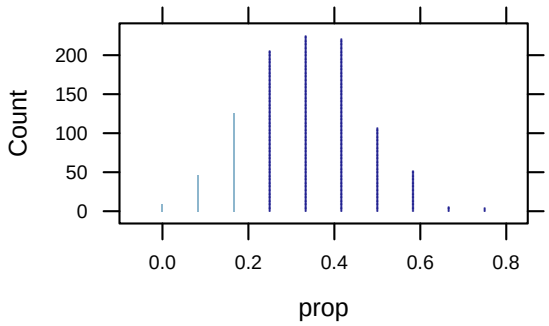
   For the **p-value**, you can use the `prop()` function and input `(prop <= 1/6)` to find the proportion of samples that is less than or equal to the observed proportion in the data set `sim.sci`.

Figure1.8

```
dotPlot(~prop, data = sim.sci, cex = 3, width = 1/12, groups = (prop <= 1/6))
prop(~(prop <= 1/6), data = sim.sci)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.179
```



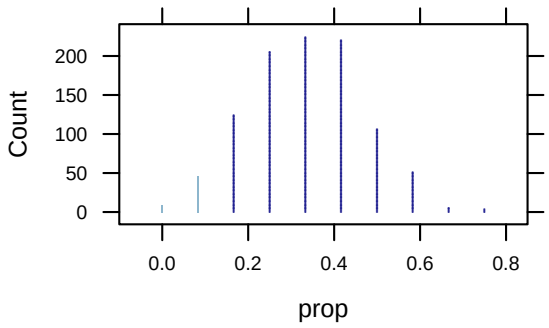
Conclusions

Figure1.9

```
dotPlot(~prop, data = sim.sci, cex = 3, width = 1/12, groups = (prop <= 1/12))
prop(~(prop <= 1/12), data = sim.sci)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.054
```



## Exploration 1.2: Tasting Water

1. $H_0$: $\pi = 1/4$

   $H_a$: $\pi < 1/4$

   Test statistic: $\hat{p} = 0.111$ (the sample proportion of 3/27)

2. We simulate a world in which $\pi = 1/4$:

Exploration1.2.18

```
sample.tap <- do(1) * rflip(27, 1/4)
sample.tap

  n heads tails   prop
1 27     6    21 0.2222

sim.tap <- do(1000) * rflip(27, 1/4)
head(sim.tap, 3)

  n heads tails   prop
1 27     4    23 0.1481

3. Strength of evidence:

 ©2014

Exploration1.2.20

```
prop(~(prop <= 3/27), data = sim.tap)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.056
```

Alternate Analysis

1. $H_0$: $\pi = 3/4$

   $H_a$: $\pi > 3/4$

   Test statistic: $\hat{p} = 0.889$ (the sample proportion of 24/27)

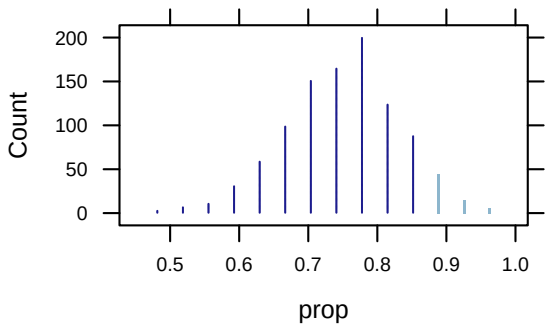
2. We simulate a world in which $\pi = 3/4$:

Exploration1.2.26

```
sim.bottled <- do(1000) * rflip(27, 3/4)
head(sim.bottled, 3)

  n heads tails   prop
1 27    21     6 0.7778
2 27    22     5 0.8148
3 27    20     7 0.7407

dotPlot(~prop, data = sim.bottled, width = 1/27, cex = 3, groups = (prop >= 24/27))
```



3. Strength of evidence:

Exploration1.2.26b

```
prop(~(prop >= 24/27), data = sim.bottled)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.062
```

## 1.3 Alternative Measure of Strength of Evidence

### Example 1.3: Heart Transplant Operations

1. $H_0$: $\pi = 0.15$
   $H_a$: $\pi > 0.15$
   Test statistic: $\hat{p} = 0.80$ (the sample proportion of 8/10)
2. We simulate a world in which $\pi = 0.15$:

Figure1.10

```
sim.heart <- do(1000) * rflip(10, 0.15)
head(sim.heart, 3)
```

```
  n heads tails prop
1 10     0    10  0.0
2 10     1     9  0.1
3 10     2     8  0.2
```

```
mean(~prop, data = sim.heart)
```

```
[1] 0.1477
```

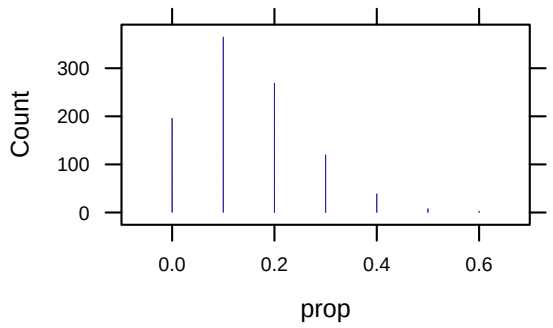
```
sd(~prop, data = sim.heart)
```

```
[1] 0.1128
```

```
favstats(~prop, data = sim.heart)
```

```
 min  Q1 median  Q3 max   mean     sd    n missing
   0 0.1    0.1 0.2 0.6 0.1477 0.1128 1000       0
```

```
dotPlot(~prop, data = sim.heart, width = 0.1, cex = 3, groups = (prop >= 8/10))
```



3. Strength of evidence:

Figure1.10b

```
prop(~(prop >= 8/10), data = sim.heart)
```

```
    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

Digging deeper into the St. George's mortality data

1. $H_0$: $\pi = 0.15$
   $H_a$: $\pi > 0.15$
   Test statistic: $\hat{p} = 0.197$ (the sample proportion of 71/361)
2. We simulate a world in which $\pi = 0.15$:

Figure1.11

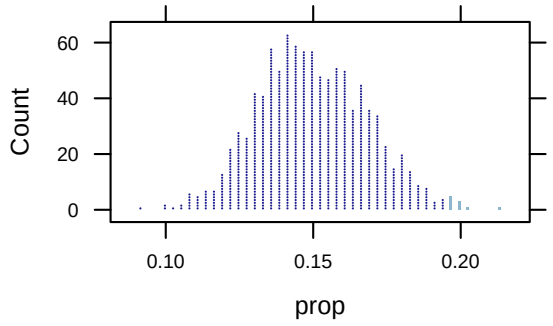
```
sim.1986 <- do(1000) * rflip(361, 0.15)
head(sim.1986, 3)

    n heads tails   prop
1 361    39   322 0.1080
2 361    44   317 0.1219
3 361    64   297 0.1773

favstats(~prop, data = sim.1986)

     min     Q1 median     Q3    max   mean      sd    n missing
 0.09141 0.1357 0.1496 0.1634 0.2133 0.1498 0.01851 1000       0

dotPlot(~prop, data = sim.1986, width = 1/361, groups = (prop >= 71/361))
```



3. Strength of evidence:

Figure1.11b

```
prop(~(prop >= 71/361), data = sim.1986)

    target level:  TRUE;  other levels:  FALSE

TRUE
0.01
```

An alternative to the p-value: Standardized value of a statistic

R can be used as a calculator so we can compute the **z-score** manually:

Example1.3

```
z <- (71/361 - 0.15) / 0.018; z   # z-score for sample size 361
```

```
[1] 2.593106
```

```
z <-  (8/10 - 0.15)  / 0.113; z   # z-score for sample size 10
```

```
[1] 5.752212
```

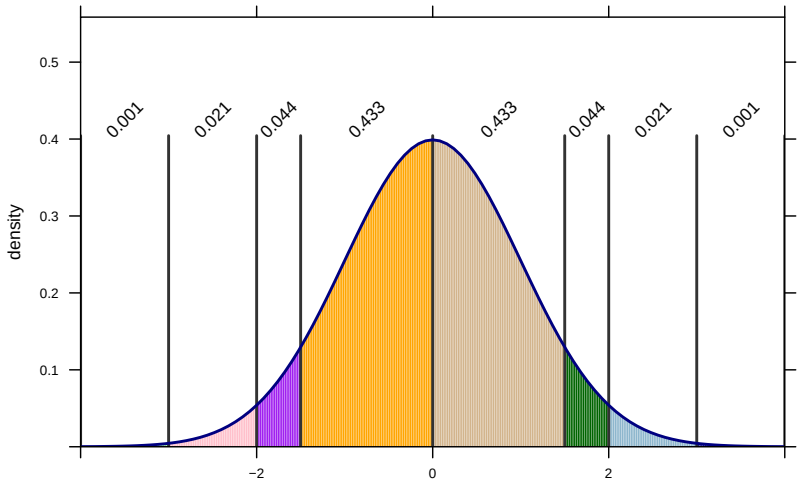
A very simple way to calculate the standardized statistic, find the p-value, and plot the bell-shaped curve is with the `xpnorm()` function. We'll examine `xpnorm()` in more detail later but for now, we just define a vector of quantiles (z-scores), `mean`, and `sd`.

Figure1.12

```
xpnorm(c(-3, -2, -1.5, 0, 1.5, 2, 3), mean = 0, sd = 1)
```

```
If X ~ N(0,1), then

P(X <= -3) = P(Z <= -3) = 0.0013
  P(X <= -2) = P(Z <= -2) = 0.0228
  P(X <= -1.5) = P(Z <= -1.5) = 0.0668
  P(X <= 0) = P(Z <= 0) = 0.5
  P(X <= 1.5) = P(Z <= 1.5) = 0.9332
  P(X <= 2) = P(Z <= 2) = 0.9772
  P(X <= 3) = P(Z <= 3) = 0.9987
P(X >  -3) = P(Z >  -3) = 0.9987
  P(X >  -2) = P(Z >  -2) = 0.9772
  P(X >  -1.5) = P(Z >  -1.5) = 0.9332
  P(X >  0) = P(Z >  0) = 0.5
  P(X >  1.5) = P(Z >  1.5) = 0.0668
  P(X >  2) = P(Z >  2) = 0.0228
  P(X >  3) = P(Z >  3) = 0.0013
[1] 0.001349898 0.022750132 0.066807201 0.500000000 0.933192799 0.977249868 0.998650102
```



In the example above, we input standardized values. However, we can input non-standardized statistics (observed statistic) with a new `mean` and `sd` in order to calculate the z-score.

 ©2014

Example1.3b

```
xpnorm(71/361, mean = 0.15, sd = 0.018, plot = FALSE)
```

```
If X ~ N(0.15,0.018), then

P(X <= 0.196675900277008) = P(Z <= 2.593) = 0.9952
P(X >  0.196675900277008) = P(Z >  2.593) = 0.0048
[1] 0.9952443
```

```
xpnorm(8/10, mean = 0.15, sd = 0.113, plot = FALSE)
```

```
If X ~ N(0.15,0.113), then

P(X <= 0.8) = P(Z <= 5.752) = 1
P(X >  0.8) = P(Z >  5.752) = 0
[1] 1
```

We'll ignore the p-values and plots for now and just realize that `xpnorm()` has computed the z-score for us so that we do not need to manually compute z by using R as a calculator.

## Exploration 1.3: Do People Use Facial Prototyping?

1. $H_0$: $\pi = 0.5$

   $H_a$: $\pi > 0.5$

   Test statistic: $\hat{p} = 0.6$ (the sample proportion of 18/30 for a fictitious class)

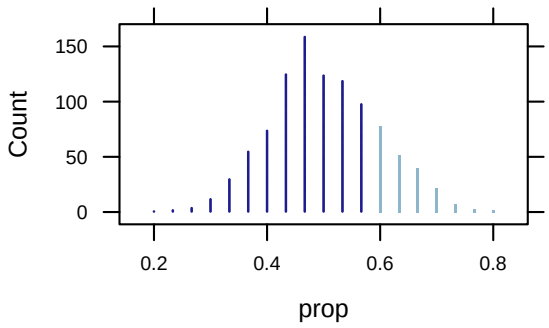
2. We simulate a world in which $\pi = 0.5$:

Exploration1.3.7

```
sim.tim <- do(1000) * rflip(30, 0.5)
head(sim.tim, 3)
```

```
  n heads tails   prop
1 30    16    14 0.5333
2 30    13    17 0.4333
3 30    14    16 0.4667
```

```
dotPlot(~prop, data = sim.tim, width = 1/30, cex = 3, groups = (prop >= 18/30))
```



3. Strength of evidence:

Exploration1.3.7b

```
prop(~(prop >= 18/30), data = sim.tim)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.197
```

Exploration1.3.8

```
mean(~prop, data = sim.tim)

[1] 0.5004

sd <- sd(~prop, data = sim.tim)
sd  # assign the standard deviation to sd

[1] 0.09459804

z <- (0.6 - 0.5)/sd
z  # z-score using the assigned sd

[1] 1.057104
```

Again, we can input the observed statistic, mean, and standard deviation to `xpnorm()` for the standardized statistic:

Figure1.13

```
xpnorm(0.6, mean = 0.5, sd = sd, plot = FALSE)

If X ~ N(0.5,0.094598037975366), then

P(X <= 0.6) = P(Z <= 1.057) = 0.8548
P(X >  0.6) = P(Z >  1.057) = 0.1452
[1] 0.854768
```

## 1.4 What Impacts Strength of Evidence?

### Example 1.4: Predicting Elections from Faces?

1. $H_0$: $\pi = 0.5$
   $H_a$: $\pi > 0.5$
   Test statistic: $\hat{p} = 0.719$ (the sample proportion of 23/32)
2. We simulate a world in which $\pi = 0.5$:

Figure1.14

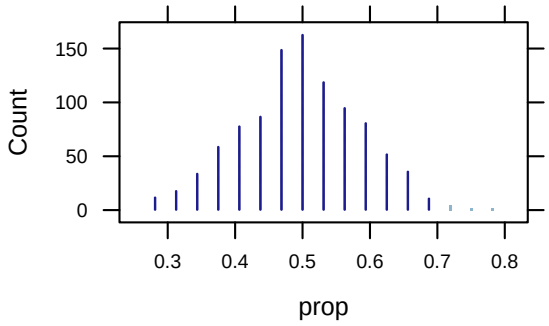
```
sim.senate <- do(1000) * rflip(32, 0.5)
head(sim.senate, 3)

  n heads tails   prop
1 32    19    13 0.5938
2 32    15    17 0.4688
3 32    15    17 0.4688

favstats(~prop, data = sim.senate)

    min     Q1 median     Q3    max   mean      sd    n missing
 0.2812 0.4375    0.5 0.5625 0.7812 0.4968 0.08796 1000       0

dotPlot(~prop, data = sim.senate, groups = (prop >= 23/32), width = 1/32, cex = 3)
```



3. Strength of evidence:

Figure1.14b

```
prop(~(prop >= 23/32), data = sim.senate)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.006
```

Strength of evidence with the standardized statistic:

Figure1.14c

```
mean(~prop, data = sim.senate)

[1] 0.49675
```

```
sd <- sd(~prop, data = sim.senate)
sd

[1] 0.08796254

xpnorm(23/32, 0.5, sd, plot = FALSE)

If X ~ N(0.5,0.0879625447806297), then

P(X <= 0.71875) = P(Z <= 2.487) = 0.9936
P(X >  0.71875) = P(Z >  2.487) = 0.0064
[1] 0.9935561
```

## What impacts strength of evidence?

Figure1.15

```
senate.32 <- do(1000) * rflip(32, 0.5)
dotPlot(~prop, data = senate.32, xlim = c(0.1, 0.9), cex = 5)
senate.128 <- do(1000) * rflip(128, 0.5)
dotPlot(~prop, data = senate.128, xlim = c(0.1, 0.9), cex = 5)
senate.256 <- do(1000) * rflip(256, 0.5)
dotPlot(~prop, data = senate.256, xlim = c(0.1, 0.9), cex = 5)
```

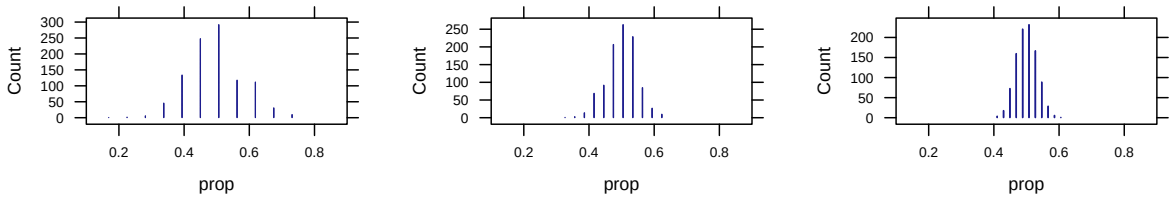


Figure1.15b

```
sd(~prop, data = senate.32)

[1] 0.08523935

sd(~prop, data = senate.128)

[1] 0.04625803

sd(~prop, data = senate.256)

[1] 0.03135788
```

Figure1.15c

```
prop(~(prop >= 23/32), data = senate.32)
```

 ©2014

```
    target level:  TRUE;  other levels:  FALSE

TRUE
0.01

prop(~(prop >= 23/32), data = senate.128)

    target level:  TRUE;  other levels:  FALSE

TRUE
   0

prop(~(prop >= 23/32), data = senate.256)

    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

1. $H_0$: $\pi = 0.5$
   $H_a$: $\pi \neq 0.5$
   Test statistic: $\hat{p} = 0.719$ (the sample proportion of 23/32)
2. We use the simulated world in which $\pi = 0.5$:

```
dotPlot(~ prop, data = sim.senate, groups = (prop >= 23/32 | prop <= 9/32),
        width = 1/32, cex = 3)
```

Figure1.16

   Notice that because we are doing a two-sided test, we differentiate the samples with proportions greater than or equal to 23/32 and proportions less than or equal to 9/32 (the proportion that is as extreme as 23/32) by using the bar |.
3. Strength of evidence:

```
prop(~(prop <= 9/32 | prop >= 23/32), data = sim.senate)

    target level:  TRUE;  other levels:  FALSE
```

Figure1.16b

```
 TRUE
0.018
```

Follow-up Study

1. $H_0$: $\pi = 0.5$

   $H_a$: $\pi \neq 0.5$

   Test statistic: $\hat{p} = 0.677$ (the sample proportion of 189/279)

2. We simulate a world in which $\pi = 0.5$:

Figure1.17

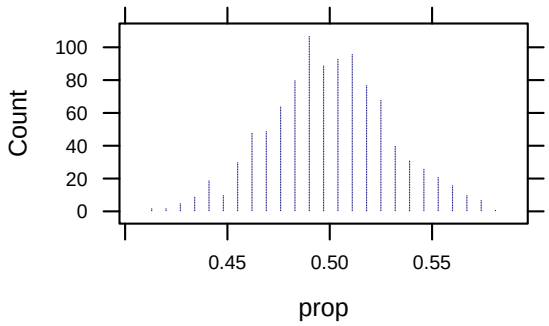
```
sim.house <- do(1000) * rflip(279, 0.5)
head(sim.house, 3)
```

```
    n heads tails   prop
1 279   144   135 0.5161
2 279   153   126 0.5484
3 279   138   141 0.4946
```

```
favstats(~prop, data = sim.house)
```

```
    min     Q1 median     Q3    max   mean      sd    n missing
 0.4122 0.4803 0.4982 0.5197 0.5842 0.4994 0.02986 1000       0
```

```
dotPlot(~prop, data = sim.house, groups = (prop >= 189/279 | prop <= 90/279), width = 0.007)
```



3. Strength of evidence:

Figure1.17b

```
prop(~(prop >= 189/279 | prop <= 90/279), data = sim.house)
```

```
    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

Strength of evidence with the standardized statistic:

Figure1.17c

```
mean(~prop, data = sim.house)

[1] 0.4994265

sd <- sd(~prop, data = sim.house)
sd

[1] 0.02986371

xpnorm(189/279, 0.5, sd, plot = FALSE)

If X ~ N(0.5,0.0298637127792574), then

P(X <= 0.67741935483871) = P(Z <= 5.941) = 1
P(X >  0.67741935483871) = P(Z >  5.941) = 0
[1] 1
```

## Exploration 1.4: Competitive Advantage to Uniform Colors?

1. $H_0$: $\pi = 0.5$

   $H_a$: $\pi > 0.5$

   Test statistic: $\hat{p} = 0.543$ (the sample proportion of 248/457)

2. We simulate a world in which $\pi = 0.5$:

Exploration1.4.3

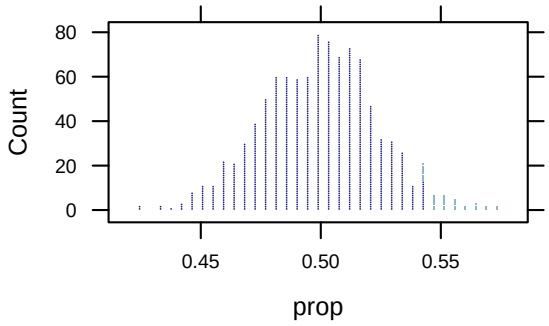
```
sim.red <- do(1000) * rflip(457, 0.5)
head(sim.red, 3)

    n heads tails   prop
1 457   230   227 0.5033
2 457   232   225 0.5077
3 457   237   220 0.5186

favstats(~prop, data = sim.red)

    min     Q1 median     Q3    max   mean      sd    n missing
 0.4245 0.4836 0.5011 0.5164 0.5733 0.5005 0.02387 1000       0

dotPlot(~prop, data = sim.red, groups = (prop >= 0.543), width = 2/457)
```



3. Strength of evidence:

Exploration1.4.3b

```
prop(~(prop >= 0.543), data = sim.red)

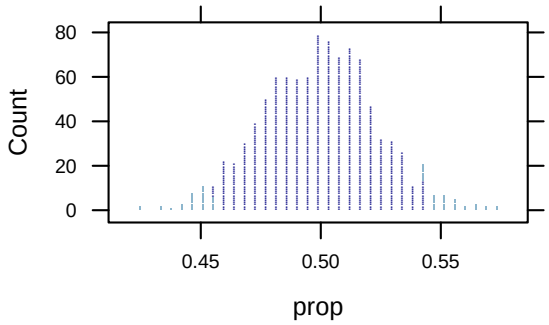
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.036
```

1. $H_0$: $\pi = 0.5$
   $H_a$: $\pi \neq 0.5$
   Test statistic: $\hat{p} = 0.543$ (the sample proportion of 248/457)
2. We use the simulated world in which $\pi = 0.5$ from the one-sided test:

Exploration1.4.5

```
dotPlot(~prop, data = sim.red, groups = (prop <= 0.457 | prop >= 0.543), width = 2/457)
```



3. Strength of evidence:

## 1.5 Inference on a single proportion: Theory-based approach

### Example 1.5: Halloween Treats

1. $H_0$: $\pi = 0.5$

   $H_a$: $\pi \neq 0.5$

   Test statistic: $\hat{p} = 0.523$ (the sample proportion of 148/283)

2. We simulate a world in which $\pi = 0.5$:

Figure1.19

```
sim.candy <- do(1000) * rflip(283, 0.5)
head(sim.candy, 3)

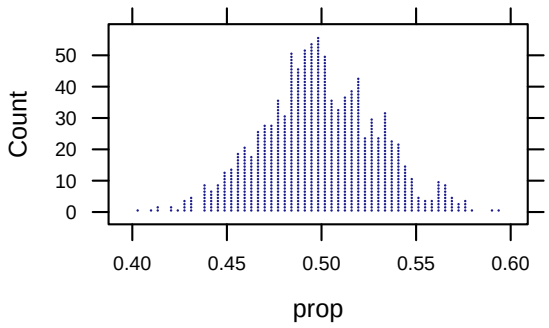
    n heads tails   prop
1 283   137   146 0.4841
2 283   157   126 0.5548
3 283   132   151 0.4664

favstats(~prop, data = sim.candy)

    min     Q1 median     Q3    max   mean      sd    n missing
 0.4028 0.4806 0.4982 0.5194 0.5936 0.4991 0.03041 1000       0

dotPlot(~prop, data = sim.candy, width = 1/283)
```

 ©2014



Theory-based approach (One proportion z test)

Calculating predicted standard deviation:

Example1.5

```
mean <- 0.5
n <- 283
sd <- sqrt(mean * (1 - mean)/n)
sd
```

```
[1] 0.02972191
```

Calculating z-score:

Example1.5b

```
z <- (0.523 - mean)/sd
z
```

```
[1] 0.7738398
```

```
xpnorm(148/283, 0.5, sd, plot = FALSE)
```

```
If X ~ N(0.5,0.0297219149138882), then

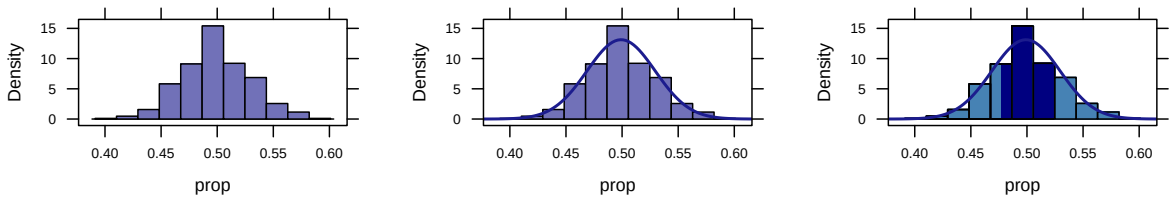
P(X <= 0.522968197879859) = P(Z <= 0.773) = 0.7802
P(X >  0.522968197879859) = P(Z >  0.773) = 0.2198
[1] 0.7801707
```

To overlay a normal approximation, let's graph a histogram using `histogram()` instead of a dotplot:

Figure1.20

```
histogram(~prop, data = sim.candy)
histogram(~prop, data = sim.candy, fit = "normal")
histogram(~prop, data = sim.candy, fit = "normal", group = cut(prop, c(0, 135/283, 148/283,
    1)), fcol = c("steelblue", "navy", "steelblue"))
prop(~(prop <= 135/283 | prop >= 148/283), data = sim.candy)
```

```
 TRUE
0.472
```



The two main functions we need for working with normal distributions are `pnorm()` and `qnorm()`. `pnorm()` computes the proportion of a normal distribution below a specified value:

$$\texttt{pnorm(x,mean=}\mu\texttt{, sd=}\sigma\texttt{)} = \Pr(X \leq x)$$

when $X \sim \text{Norm}(\mu, \sigma)$.

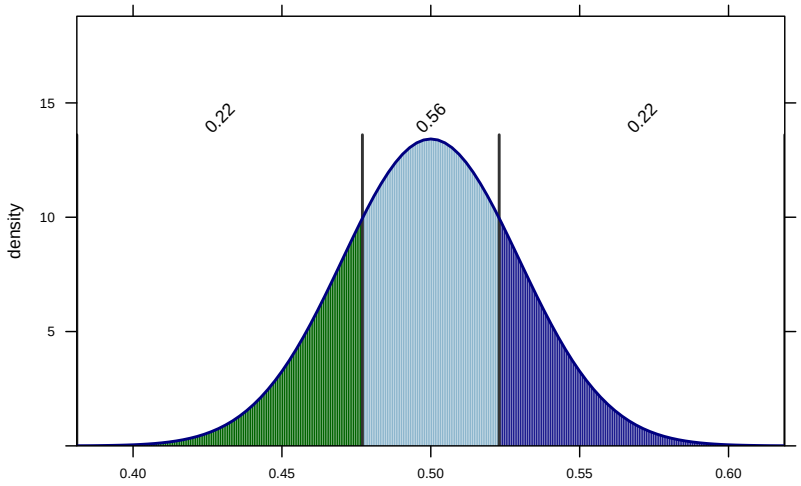
We can obtain arbitrary probabilities using `pnorm()` We can now examine the rest of the output from `xpnorm()`, which is an augmented version of `pnorm()`. Because it's a two-sided test, we can input both the observed statistic (148/283) and the statistic that is as extreme as the observed (135/283).

Figure1.20b

```
xpnorm(c(135/283, 148/283), 0.5, sd)
```

```
If X ~ N(0.5,0.0297219149138882), then

P(X <= 0.477031802120141) = P(Z <= -0.773) = 0.2198
  P(X <= 0.522968197879859) = P(Z <= 0.773) = 0.7802
P(X >  0.477031802120141) = P(Z >  -0.773) = 0.7802
  P(X >  0.522968197879859) = P(Z >  0.773) = 0.2198
[1] 0.2198293 0.7801707
```



The output gives the z-scores for both statistics and the p-value. We know now that this p-value is found using

the predicted standard deviation and normal approximation. The p-value for the two-sided test is the sum of P($Z$ <= −0.773) and P($Z$ > 0.773).

We can also use the just observed statistic as we have done before but only we will need to change the `lower.tail` to `FALSE`.

Figure1.20c

```
xpnorm(148/283, 0.5, sd, lower.tail = FALSE, plot = FALSE)
```

```
If X ~ N(0.5,0.0297219149138882), then

P(X <= 0.522968197879859) = P(Z <= 0.773) = 0.7802
P(X >  0.522968197879859) = P(Z >  0.773) = 0.2198
[1] 0.2198293
```

```
2 * xpnorm(148/283, 0.5, sd, lower.tail = FALSE, plot = FALSE)
```

```
If X ~ N(0.5,0.0297219149138882), then

P(X <= 0.522968197879859) = P(Z <= 0.773) = 0.7802
P(X >  0.522968197879859) = P(Z >  0.773) = 0.2198
[1] 0.4396586
```

This results in the p-value of the alternative hypothsis that $\pi$ is greater than the observed statistic (the default is the alternative hypothsis that $\pi$ is less than the observed statistic). For the two-sided test, we have multiplied the resulting p-value by two.

The function `pnorm()` can be used just to find the p-value:

Figure1.20d

```
2 * pnorm(148/283, 0.5, sd, lower.tail = FALSE)
```

```
[1] 0.4396586
```

Further, we can input the standardized statistic (z-score) to find the p-value:

Figure1.20e

```
2 * pnorm(z, 0, 1, lower.tail = FALSE)
```

```
[1] 0.4390255
```

The most convenient way to find the p-value for a proportion using normal approximation is to use `prop.test()` by inputing the number of sucesses and the number of samples:

Example1.5c

```
prop.test(148, n = 283)
```

```
1-sample proportions test with continuity correction
```

```
data:  148 out of 283
X-squared = 0.50883, df = 1, p-value = 0.4756
alternative hypothesis: true p is not equal to 0.5
95 percent confidence interval:
 0.4631063 0.5821963
sample estimates:
        p
0.5229682
```

Note that the default for the prop test is with a $\pi = 0.5$, two-sided test, and a continuity correction. The continuity correction results in a more accurate p-value but if you want the p-value found with `pnorm()` we can change the default.

Figure1.5d

```
prop.test(148, 283, correct = FALSE)
```

```
1-sample proportions test without continuity correction

data:  148 out of 283
X-squared = 0.59717, df = 1, p-value = 0.4397
alternative hypothesis: true p is not equal to 0.5
95 percent confidence interval:
 0.4648584 0.5804628
sample estimates:
        p
0.5229682
```

A situation where a theory-based approach doesn't work

Example1.5e

```
mean <- 1/3
n <- 12
sd <- sqrt(mean * (1 - mean)/n)
sd
```

```
[1] 0.1360828
```

Figure1.21

```
dotPlot(~prop, data = sim.sci, group = (prop <= 1/6), width = 1/12, cex = 3)
prop(~(prop <= 1/6), data = sim.sci)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.179
```

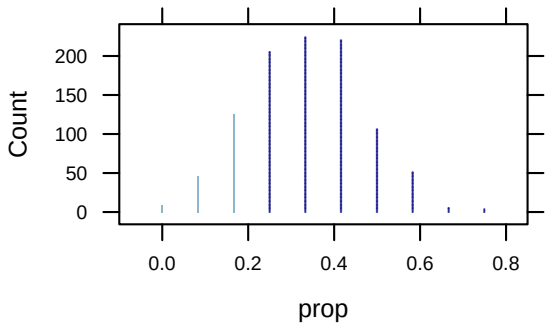

Figure1.21b

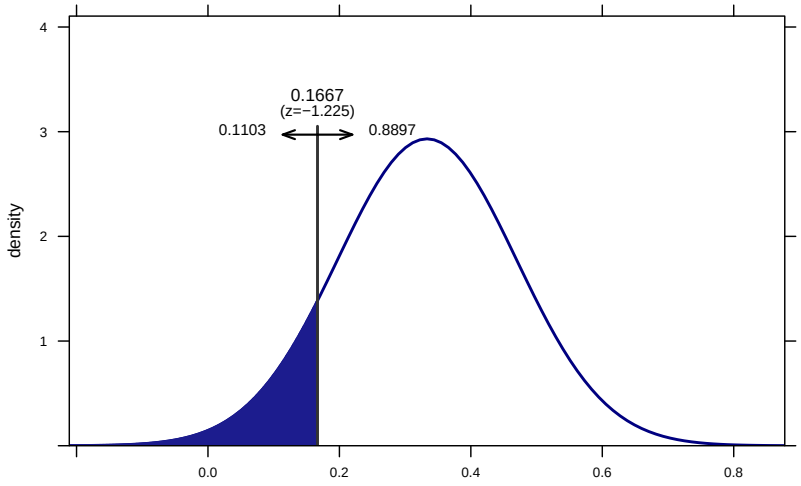
```
xpnorm(1/6, 1/3, sd)
```

```
If X ~ N(0.333333333333333,0.136082763487954), then

P(X <= 0.166666666666667) = P(Z <= -1.225) = 0.1103
P(X >  0.166666666666667) = P(Z >  -1.225) = 0.8897
[1] 0.1103357
```



## Exploration 1.5: Calling Heads or Tails

1. $H_0$: $\pi = 0.5$
   $H_a$: $\pi > 0.5$
   Test statistic: $\hat{p} = 0.651$ (the sample proportion of 54/83)
2. We simulate a world in which $\pi = 0.5$:

Exploration1.5.5

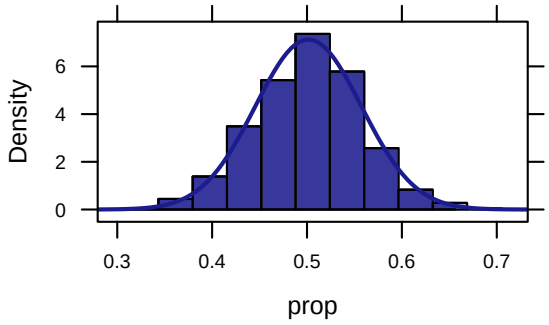
```
sim.heads <- do(1000) * rflip(83, 0.5)
head(sim.heads, 3)
```

```
   n heads tails   prop
1 83    46    37 0.5542
2 83    43    40 0.5181
3 83    41    42 0.4940
```

```
favstats(~prop, data = sim.heads)
```

```
    min     Q1 median     Q3    max   mean      sd    n missing
 0.3253 0.4699  0.506 0.5422 0.6867 0.5014 0.05601 1000       0
```

```
histogram(~prop, data = sim.heads, groups = (prop >= 54/83), fit = "normal")
```



3. Strength of evidence

Exploration1.5.5b

```
prop(~(prop >= 54/83), data = sim.heads)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.005
```

Normal approximation using simulated sd:

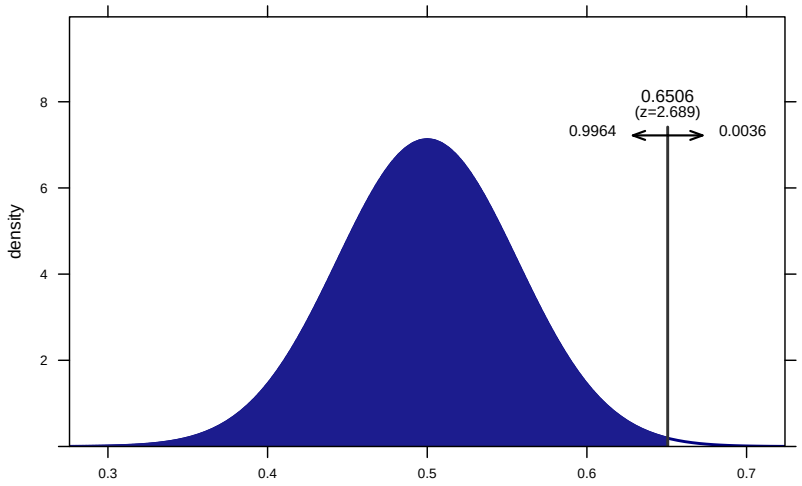
Exploration1.5.5c

```
sd <- sd(~prop, data = sim.heads)
xpnorm(54/83, 0.5, sd, lower.tail = FALSE)
```

```
If X ~ N(0.5,0.0560149681052275), then

P(X <= 0.650602409638554) = P(Z <= 2.689) = 0.9964
P(X >  0.650602409638554) = P(Z >  2.689) = 0.0036
[1] 0.003587508
```

 ©2014



Formulas

Exploration1.5.8

```
sd <- sqrt(0.5 * (1 - 0.5)/83)
sd
```

```
[1] 0.05488213
```

Exploration1.5.9

```
xpnorm(54/83, 0.5, sd, plot = FALSE, lower.tail = FALSE)
```

```
If X ~ N(0.5,0.0548821299948452), then

P(X <= 0.650602409638554) = P(Z <= 2.744) = 0.997
P(X >  0.650602409638554) = P(Z >  2.744) = 0.003
[1] 0.003033792
```

```
prop.test(54, 83, alt = "greater", correct = FALSE)
```

```
1-sample proportions test without continuity correction

data:  54 out of 83
X-squared = 7.5301, df = 1, p-value = 0.003034
alternative hypothesis: true p is greater than 0.5
95 percent confidence interval:
 0.5610038 1.0000000
sample estimates:
        p
0.6506024
```

Follow-up Analysis #1

1. $H_0$: $\pi = 0.5$
   $H_a$: $\pi \neq 0.5$
   Test statistic: $\hat{p} = 0.70$ (the sample proportion)
2. Normal approximation using predicted sd:

Exploration1.5.12

```
sd <- sqrt(0.5 * (1 - 0.5)/83)
sd

[1] 0.05488213

2 * xpnorm(0.7, 0.5, sd, plot = FALSE, lower.tail = FALSE)

If X ~ N(0.5,0.0548821299948452), then

P(X <= 0.7) = P(Z <= 3.644) = 0.9999
P(X >  0.7) = P(Z >  3.644) = 1e-04
[1] 0.0002682525
```

   Approximate test for proportions without continuity correction:

Exploration1.5.12b

```
prop.test(58.1, 83, correct = FALSE)  # 58.1 = 0.70 * 83

1-sample proportions test without continuity correction

data:  58.1 out of 83
X-squared = 13.28, df = 1, p-value = 0.0002683
alternative hypothesis: true p is not equal to 0.5
95 percent confidence interval:
 0.5943661 0.7879397
sample estimates:
  p
0.7
```

Follow-up Analysis # 2

1. $H_0$: $\pi = 0.5$
   $H_a$: $\pi \neq 0.5$
   Test statistic: $\hat{p} = 0.875$ (the sample proportion of $7/8$)
2. We simulate a world in which $\pi = 0.5$:

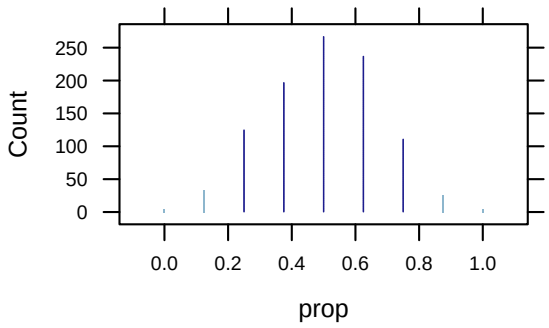
Exploration1.5.13

```
sim.small <- do(1000) * rflip(8, 0.5)
head(sim.small, 3)

  n heads tails prop
1 8     4     4 0.50
2 8     4     4 0.50
3 8     2     6 0.25

dotPlot(~prop, data = sim.small, groups = (prop <= 0.125 | prop >= 0.875), width = 1/8, cex = 3)
```

 ©2014



3. Strength of evidence:

Exploration1.5.13b

```
prop(~(prop <= 0.125 | prop >= 0.875), data = sim.small)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.063
```

Approximate test for proportions without continuity correction:

Exploration1.5.13c

```
prop.test(7, 8, correct = FALSE)

1-sample proportions test without continuity correction

data:  7 out of 8
X-squared = 4.5, df = 1, p-value = 0.03389
alternative hypothesis: true p is not equal to 0.5
95 percent confidence interval:
 0.5291118 0.9775825
sample estimates:
    p
0.875
```

There is also another test that will compute the p-value for a proportion and that the binomial test. `binom.test()` utilizes a binomial probability distribution while `prop.test()` utilizes a normal probability distribution. The tests are similar but the binomial test will result in the most accurate p-value.

```
binom.test(7, 8)

Exact binomial test (with Score CI)

data:  7 out of 8
number of successes = 7, number of trials = 8, p-value = 0.07031
alternative hypothesis: true probability of success is not equal to 0.5
95 percent confidence interval:
 0.4734903 0.9968403
sample estimates:
probability of success
                 0.875
```

```
binom.test(58, 83)
```

```
Exact binomial test (with Score CI)

data:  58 out of 83
number of successes = 58, number of trials = 83, p-value = 0.0003783
alternative hypothesis: true probability of success is not equal to 0.5
95 percent confidence interval:
 0.5882227 0.7946876
sample estimates:
probability of success
             0.6987952
```

# 2 Generalization: How Broadly Do the Results Apply?

## 2.1 Sampling from a Finite Population

### Example 2.1A: Sampling Students

```
head(CollegeMidwest, 8)
```

Table2.1

```
  onCampus cumGPA
1        N   2.92
2        N   3.59
3        N   3.36
4        N   2.47
5        N   3.46
6        Y   2.98
7        Y   3.07
8        Y   3.79
```

In chapter one, we used **histograms** a few times instead of dotplots and changed their widths. You can also control the number of bins by defining `nint,` or `n` for short.

Figure2.1

```
histogram(~CumGpa, data = CollegeMidwest, n = 24)
```

```
Error in eval(expr, envir, enclos):  object 'CumGpa' not found
```

```
bargraph(~OnCampus, data = CollegeMidwest)
```

```
Error in eval(expr, envir, enclos):  object 'OnCampus' not found
```

#### Simple Random Samples

For a **simple random sample** of a data set, we use `sample()` and define the size of the same we want.

Table2.2

```
sample1 <- sample(CollegeMidwest, 30)
sample1
```

```
     OnCampus CumGpa orig.ids
1054        Y   3.90     1054
940         Y   3.40      940
1828        Y   3.33     1828
1668        Y   3.85     1668
2161        Y   3.76     2161
2637        Y   2.91     2637
1364        Y   3.91     1364
818         Y   2.66      818
1233        Y   3.91     1233
1817        N   3.69     1817

398         Y   3.51      398
2495        Y   3.54     2495
2516        Y   3.05     2516
1486        N   3.74     1486
1837        Y   2.58     1837
1798        Y   3.35     1798
2571        Y   2.86     2571
2099        Y   3.51     2099
1980        Y   3.23     1980
698         Y   4.00      698
616         Y   2.36      616
70          N   3.58       70
1313        Y   3.25     1313
1952        Y   2.12     1952
1345        Y   3.95     1345
1503        N   3.39     1503
2115        Y   3.98     2115
2652        Y   2.76     2652
783         N   3.71      783
```

```
sample2 <- sample(CollegeMidwest, 30)
sample3 <- sample(CollegeMidwest, 30)
sample4 <- sample(CollegeMidwest, 30)
sample5 <- sample(CollegeMidwest, 30)
```

Table2.3

```
mean(~CumGpa, data = sample1)
```

```
[1] 3.379333
```

```
mean(~CumGpa, data = sample2)
```

```
[1] 3.378667
```

```
mean(~CumGpa, data = sample3)
```

```
[1] 3.317667
```

 ©2014

```
mean(~CumGpa, data = sample4)

[1] 3.261667

mean(~CumGpa, data = sample5)

[1] 3.112

prop(~OnCampus, level = "Y", data = sample1)

    target level:  Y;  other levels:  N

        Y
0.8333333

prop(~OnCampus, level = "Y", data = sample2)

    target level:  Y;  other levels:  N

        Y
0.7666667

prop(~OnCampus, level = "Y", data = sample3)

    target level:  Y;  other levels:  N

        Y
0.6666667

prop(~OnCampus, level = "Y", data = sample4)

    target level:  Y;  other levels:  N

  Y
0.8

prop(~OnCampus, level = "Y", data = sample5)

    target level:  Y;  other levels:  N

  Y
0.8
```

Notice the `level` in order to find the proportion of students who said "yes" instead of the default "no".

Similar to the simulation of random processes in chapter one, we can repeat taking different simple random samples. Conveniently, R will let you set `data=` to a simple random sample so we can repeat finding the mean or the proportion of a different simple random sample many times.

Figure2.2

```

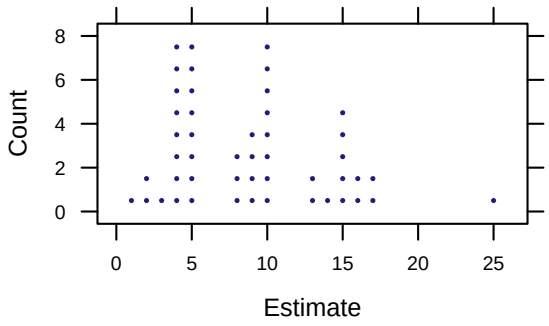
favstats(~Estimate, data = sample1)

 min   Q1 median Q3 max  mean    sd  n missing
   1 4.75      9 13  25 8.875 5.168 48       0

dotPlot(~Estimate, data = sample1, width = 1, cex = 0.3)
```



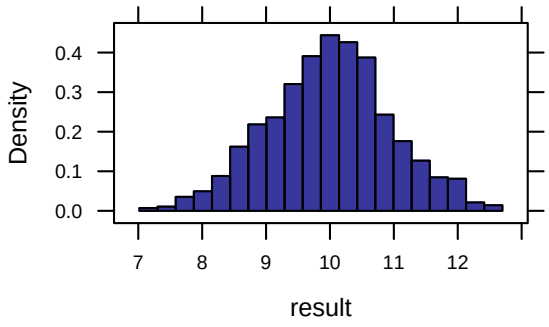
1. $H_0$: $\mu = 10$
   $H_a$: $\mu \neq 10$
   Test statistic: $\bar{x} = 13.71$ (the sample mean)
2. We simulate random samples from a finite population:

Figure2.8

```
sim.time <- do(1000) * mean(~Estimate, data = sample(TimePopulation, 48))
head(sim.time, 3)

  result
1  8.896
2  9.875
3 10.729

histogram(~result, data = sim.time, groups = (result <= 6.29 | result >= 13.71), nint = 20,
    center = 10)
```



3. Strength of evidence:

Figure2.8b

```
prop(~(result <= 6.29 | result >= 13.71), data = sim.time)

    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

Strength of evidence with the standardized statistic:

Figure2.8c

```
mean(~result, data = sim.time)

[1] 9.994021

sd <- sd(~result, data = sim.time)
sd

[1] 0.961743

xpnorm(13.71, 10, sd, lower.tail = FALSE, plot = FALSE)

If X ~ N(10,0.961742964079301), then

P(X <= 13.71) = P(Z <= 3.858) = 0.9999
P(X >  13.71) = P(Z >  3.858) = 1e-04
[1] 5.725771e-05
```

Theory-based approach: One-sample t-test

Example2.2

```
xbar <- 13.71
mu <- 10
s <- 6.5
n <- 48
t <- (xbar - mu)/(s/sqrt(n))
t

[1] 3.954405
```

Figure2.9

```
histogram(~result, data = sim.time, groups = (result <= 6.29 | result >= 13.71), nint = 20,
    center = 10, fit = "t")
```

 ©2014

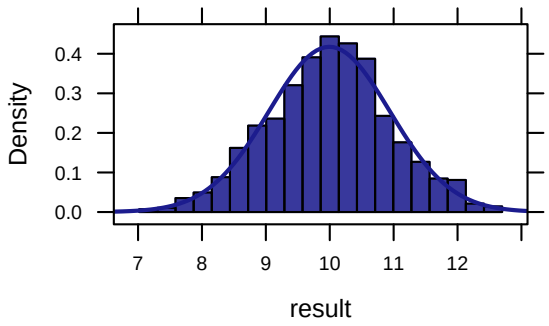


Figure2.10

```
2 * pt(t, df = 47, lower.tail = FALSE)
```

```
[1] 0.0002570976
```

Alternative Analysis: What about the median?

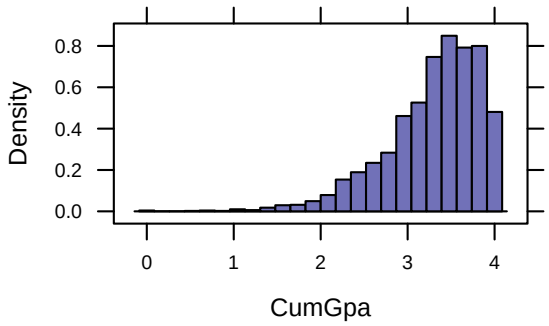
Figure2.11

```
sim.median <- do(1000) * median(~Estimate, data = sample(TimePopulation, 48))
head(sim.median, 3)
```

```
  result
1      9
2      8
3     10
```

```
histogram(~result, data = sim.median, groups = (result < 8 | result > 12), width = 0.5, type = "count")
prop(~(result < 8 | result > 12), data = sim.median)
```

```
 TRUE
0.111
```



## Exploration 2.2: Sleepless Nights?

```
head(SleepTimes, 3)
```
Exploration2.2.1

```
  sleepHrs
1      7.0
2      5.5
3      8.0
```

### Shape

```
histogram(~SleepHrs, data = SleepTimes, nint = 15)
```
Exploration2.2.10

```
Error in eval(expr, envir, enclos):  object 'SleepHrs' not found
```

### Center

```
mean(~SleepHrs, data = SleepTimes)
```
Exploration2.2.11

```
Error in eval(expr, envir, enclos):  object 'SleepHrs' not found
```

```
median(~SleepHrs, data = SleepTimes)
```
Exploration2.2.16

```
Error in eval(expr, envir, enclos):  object 'SleepHrs' not found
```

### Variability

```
sd(~SleepHrs, data = SleepTimes)
```
Exploration2.2.18

```
Error in eval(expr, envir, enclos):  object 'SleepHrs' not found
```

### Unusual observations

We could examine the entire data set to find any outliers but there is a quicker way to see if there potential outliers. The `bwplot()` function plots a box-and-whisker plot which identifies *possible* outliers with a dot beyond the whiskers.

 ©2014

Exploration2.2.20

```
bwplot(~SleepHrs, data = SleepTimes)
```

```
Error in eval(expr, envir, enclos):  object 'SleepHrs' not found
```

Instead of using the hypothetical population provided in the applet, we can create our own hypothetical population by assigning a variable (SleepHrs) a random normal distribution (rnorm()) of count (18000), mean (8 hrs), and standard deviation (1.5 hrs). Additionally, let's round each value to the nearest hundredth (2) using round()

Exploration2.2.24

```
Pop1 <- data.frame(SleepHrs = round(rnorm(18000, 8, 1.5), 2))
head(Pop1)
```

```
  SleepHrs
1     7.91
2     6.46

## Exploration 3.1: Kissing Right?

1. $H_0$: $\pi = 0.5$

   $H_a$: $\pi > 0.5$

   Test statistic: $\hat{p} = 0.645$ (the sample proportion of 80/124)

2. We simulate a world in which $\pi = 0.5$:

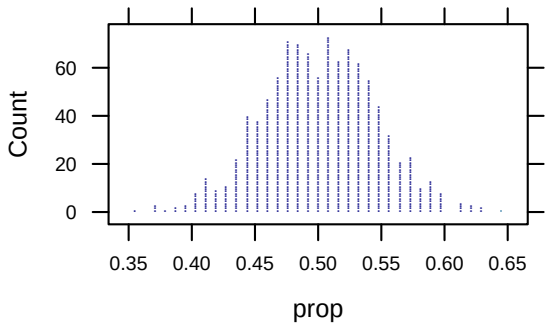
Exploration3.1.7

```
sim.kiss <- do(1000) * rflip(124, 0.5)
head(sim.kiss, 3)
```

```
    n heads tails   prop
1 124    60    64 0.4839
2 124    62    62 0.5000
3 124    60    64 0.4839
```

```
dotPlot(~prop, data = sim.kiss, groups = (prop >= 0.645), width = 0.001)
```

 ©2014



3. Strength of evidence:

Exploration3.1.7b

```
favstats(~prop, data = sim.kiss)

       min        Q1 median        Q3       max      mean         sd    n missing
 0.3548387 0.4677419    0.5 0.5322581 0.6451613 0.5010484 0.04442183 1000       0

prop(~(prop >= 0.645), data = sim.kiss)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.001
```

Approximate test for proportions:

Exploration3.1.7c

```
prop.test(80, 124, alt = "greater")

1-sample proportions test with continuity correction

data:  80 out of 124
X-squared = 9.879, df = 1, p-value = 0.0008359
alternative hypothesis: true p is greater than 0.5
95 percent confidence interval:

## 3.2 2SD and Theory-Based Confidence Intervals for a Single Proportion

### Example 3.2: The Afforable Care Act

An easy way to find a confidence interval in R is to use `prop.test()` or `binom.test()` which by default calculates a 95% confidence interval in its results.

Example3.2

```
binom.test(713, 1034)  # 713 = 1034 * 0.69
```

```
Exact binomial test (with Score CI)

data:  713 out of 1034
number of successes = 713, number of trials = 1034, p-value < 2.2e-16
alternative hypothesis: true probability of success is not equal to 0.5
95 percent confidence interval:
 0.6603601 0.7176665
sample estimates:
probability of success
             0.6895551
```

#### Theory-Based Approach

Figure3.6

```
xpnorm(c(-1.645, 1.645), 0, 1)
```

```
If X ~ N(0,1), then
```

```
P(X <= -1.645) = P(Z <= -1.645) = 0.05
  P(X <= 1.645) = P(Z <= 1.645) = 0.95
P(X >  -1.645) = P(Z >  -1.645) = 0.95
  P(X >  1.645) = P(Z >  1.645) = 0.05
[1] 0.04998491 0.95001509

xpnorm(c(-1.96, 1.96), 0, 1)

If X ~ N(0,1), then

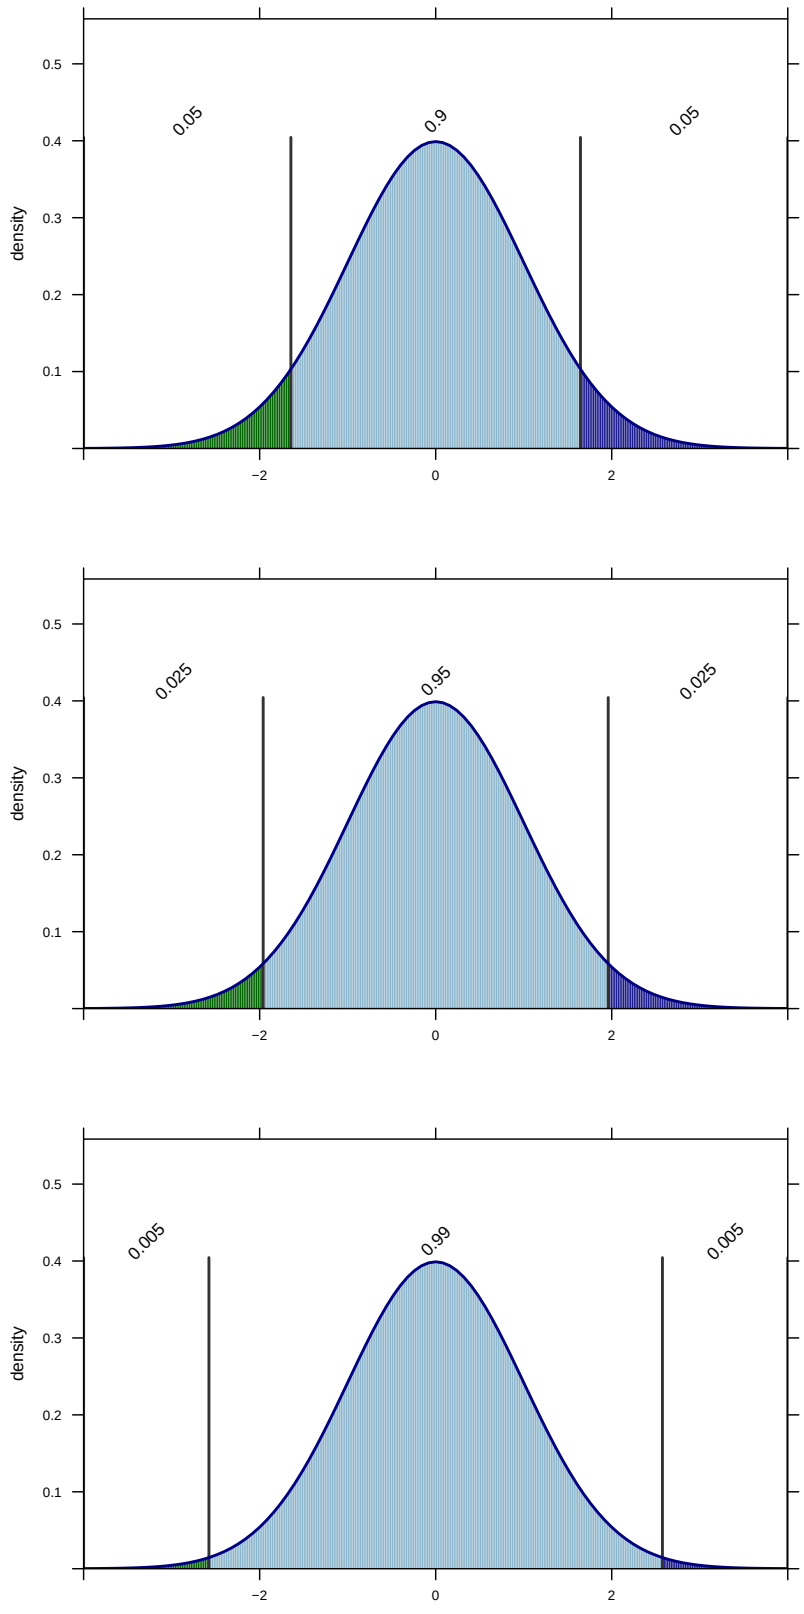
P(X <= -1.96) = P(Z <= -1.96) = 0.025
  P(X <= 1.96) = P(Z <= 1.96) = 0.975
P(X >  -1.96) = P(Z >  -1.96) = 0.975
  P(X >  1.96) = P(Z >  1.96) = 0.025
[1] 0.0249979 0.9750021

xpnorm(c(-2.576, 2.576), 0, 1)

If X ~ N(0,1), then

P(X <= -2.576) = P(Z <= -2.576) = 0.005
  P(X <= 2.576) = P(Z <= 2.576) = 0.995
P(X >  -2.576) = P(Z >  -2.576) = 0.995
  P(X >  2.576) = P(Z >  2.576) = 0.005
[1] 0.004997532 0.995002468
```

©2014



Using 2SD method and standard error of the observed sample proportion (Theory-Based Inference applet):

Figure3.7

```
n <- 1034
p.hat <- 0.69; p.hat                    # 0.69 = 713 / 1034

[1] 0.69

SE <- sqrt( p.hat * (1 - p.hat) / n )  # standard error
MoE <- 1.96 * SE; MoE                   # margin of error

[1] 0.0281904

p.hat - MoE                             # lower limit of 95% CI

[1] 0.6618096

p.hat + MoE                             # upper limit of 95% CI

[1] 0.7181904
```

## Exploration 3.2: American Exceptionalism

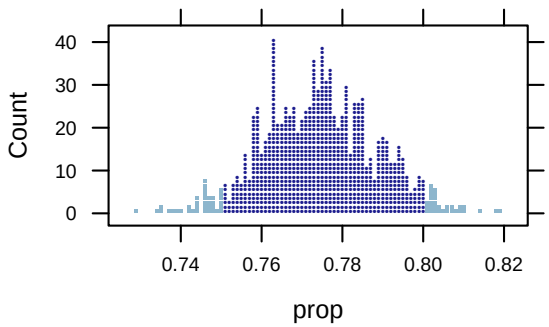
1. $H_0$: $\pi = 0.775$
   $H_a$: $\pi \neq 0.775$
   Test statistic: $\hat{p} = 0.80$ (the sample proportion of 85/1019)
2. We simulate a world in which $\pi = 0.775$:

Exploration3.2.6

```
sim.amer <- do(1000) * rflip(1019, 0.775)
head(sim.amer, 3)

     n heads tails   prop
1 1019   786   233 0.7713
2 1019   784   235 0.7694
3 1019   799   220 0.7841

dotPlot(~prop, data = sim.amer, groups = (prop <= 0.75 | prop >= 0.8), width = 0.001)
```



©2014

3. Strength of evidence:

```
favstats(~prop, data = sim.amer)
```
Exploration3.2.6b

```
       min       Q1    median        Q3       max      mean         sd    n missing
 0.7291462 0.764475 0.7742885 0.7841021 0.8194308 0.7745819 0.01393057 1000       0
```

```
prop(~(prop <= 0.75 | prop >= 0.8), data = sim.amer)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.069
```

Approximate test for proportions:

```
prop.test(815, 1019, p = 0.775)
```
Exploration3.2.6c

```

1-sample proportions test with continuity correction

data:  815 out of 1019
X-squared = 3.4544, df = 1, p-value = 0.06308
alternative hypothesis: true p is not equal to 0.775
95 percent confidence interval:
 0.7736183 0.8236924
sample estimates:
        p
0.7998037
```

Exact test for proportions:

```
binom.test(815, 1019, p = 0.775)
```
Exploration3.2.6d

```

Exact binomial test (with Score CI)

data:  815 out of 1019
number of successes = 815, number of trials = 1019, p-value = 0.06064
alternative hypothesis: true probability of success is not equal to 0.775
95 percent confidence interval:
 0.7738936 0.8239686
sample estimates:
probability of success
             0.7998037
```

1. $H_0$: $\pi = 0.5$

   $H_a$: $\pi \neq 0.5$

   Test statistic: $\hat{p} = 0.80$ (the sample proportion of 815/1019)

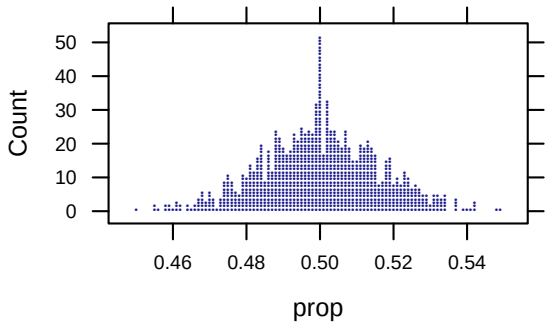
2. We simulate a world in which $\pi = 0.5$:

Exploration3.2.8

```
sim.amer2 <- do(1000) * rflip(1019, 0.5)
head(sim.amer2, 3)

     n heads tails   prop
1 1019   512   507 0.5025
2 1019   490   529 0.4809
3 1019   504   515 0.4946

dotPlot(~prop, data = sim.amer2, groups = (prop <= 0.2 | prop >= 0.8), width = 0.001)
```



3. Strength of evidence:

Exploration3.2.8b

```
favstats(~prop, data = sim.amer2)

       min        Q1    median        Q3      max      mean         sd    n missing
 0.4504416 0.4887144 0.4995093 0.5112856 0.548577 0.4999578 0.01610849 1000       0

prop(~(prop <= 0.2 | prop >= 0.8), data = sim.amer2)

    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

Approximate test for proportions:

Exploration3.2.8c

```
prop.test(815, 1019)

1-sample proportions test with continuity correction

data:  815 out of 1019
X-squared = 365.16, df = 1, p-value < 2.2e-16
alternative hypothesis: true p is not equal to 0.5
95 percent confidence interval:
 0.7736183 0.8236924
sample estimates:
        p
0.7998037
```

 ©2014

Exact test for proportions:

Exploration3.2.8d

```
binom.test(815, 1019)
```

```
Exact binomial test (with Score CI)

data:  815 out of 1019
number of successes = 815, number of trials = 1019, p-value < 2.2e-16
alternative hypothesis: true probability of success is not equal to 0.5
95 percent confidence interval:
 0.7738936 0.8239686
sample estimates:
probability of success
             0.7998037
```

Finding the standard deviation using simulated deviation:

Exploration3.2.9

```
sd <- sd(~prop, data = sim.amer)
sd
```

```
[1] 0.01393057
```

```
z <- (0.8 - 0.775)/sd
z
```

```
[1] 1.794614
```

```
xpnorm(0.8, 0.775, sd, lower.tail = FALSE, plot = FALSE)
```

```
If X ~ N(0.775,0.0139305685474377), then

P(X <= 0.8) = P(Z <= 1.795) = 0.9636
P(X >  0.8) = P(Z >  1.795) = 0.0364
[1] 0.03635757
```

Determining a 95% confidence interval using the 2SD Method and standard deviation of the null distribution:

Exploration3.2.11

```
p.hat <- 0.80          # given sample proportion
sd                     # previously found simulated standard deviation
```

```
[1] 0.01393057
```

```
MoE <- 2 * sd; MoE     # margin of error for 95% CI
```

```
[1] 0.02786114
```

```
p.hat - MoE           # lower limit of 95% CI

[1] 0.7721389

p.hat + MoE           # upper limit of 95% CI

[1] 0.8278611
```

Determining a 95% confidence interval using the 2SD Method and standard error of the observed sample proportion:

Exploration3.2.12

```
n <- 1019
p.hat <- 0.80         # given sample proportion
SE <- sqrt(p.hat * (1 - p.hat) / n); SE

[1] 0.01253063

MoE <- 2 * SE; MoE    # margin of error for 95% CI

[1] 0.02506126

p.hat - MoE           # lower limit of 95% CI

[1] 0.7749387

p.hat + MoE           # upper limit of 95% CI

[1] 0.8250613
```

Determining a 95% confidence interval using more accurate multipliers and standard error of the observed sample proportion (Theory-Based Inference applet):

Exploration3.2.13

```
n <- 1019
p.hat <- 0.80         # given sample proportion
SE <- sqrt(p.hat * (1 - p.hat) / n); SE

[1] 0.01253063

MoE <- 1.96 * SE; MoE # margin of error for 95% CI with more accurate multiplier

[1] 0.02456003

p.hat - MoE           # lower limit of 95% CI

[1] 0.77544
```

 ©2014

```
p.hat + MoE           # upper limit of 95% CI

[1] 0.82456
```

Another way to create a 95% confidence interval is to use the middle 95% of the simulated null distribution. This is not exactly the same as the interval found by the 2SD Method, but it is very close.

Exploration3.2.13b

```
cdata(0.95, prop, data = sim.amer)

      low        hi central.p
0.7468106 0.8017664 0.9500000
```

The `binom.test()` calculates the exact confidence interval for any confidence level:

Exploration3.2.13c

```
binom.test(815, 1019, p = 0.775, conf.level = 0.95)

Exact binomial test (with Score CI)

data:  815 out of 1019
number of successes = 815, number of trials = 1019, p-value = 0.06064
alternative hypothesis: true probability of success is not equal to 0.775
95 percent confidence interval:
 0.7738936 0.8239686
sample estimates:
probability of success
             0.7998037

binom.test(815, 1019, p = 0.775, conf.level = 0.99)

Exact binomial test (with Score CI)

data:  815 out of 1019
number of successes = 815, number of trials = 1019, p-value = 0.06064
alternative hypothesis: true probability of success is not equal to 0.775
99 percent confidence interval:
 0.7656447 0.8311121
sample estimates:
probability of success
             0.7998037

binom.test(815, 1019, p = 0.775, conf.level = 0.9)

Exact binomial test (with Score CI)

data:  815 out of 1019
number of successes = 815, number of trials = 1019, p-value = 0.06064
alternative hypothesis: true probability of success is not equal to 0.775
```

```
90 percent confidence interval:
 0.7780614 0.8202524
sample estimates:
probability of success
             0.7998037
```

Note that the specified $\pi$, the `p = 0.775`, only matters in calculating the p-value and does not affect the confidence interval.

## 3.3 2SD and Theory-Based Confidence Intervals for a Single Mean

### Example 3.3: Used Cars

```
head(UsedCars)
```

Figure3.9

```
  price
1 21990
2 21990
3 21987
4 20955
5 20955
6 19995
```

```
favstats(~Price, data = UsedCars)
```

```
Error in eval(expr, envir, enclos):  object 'Price' not found
```

```
histogram(~Price, data = UsedCars, type = "count", width = 2000)
```

```
Error in eval(expr, envir, enclos):  object 'Price' not found
```

Determining a 95% confidence interval using the 2SD Method and standard error of the sample population:

Example3.3

```
n <- nrow(UsedCars); n
```

```
[1] 102
```

```

## 3.4 Factors That Affect the Width of a Confidence Interval

### Example 3.4: The Afforable Care Act (continued)

Table3.5

```
confint(binom.test(713, 1034, conf.level = 0.9))  # 1034 * 0.69 = 713

probability of success                 lower                 upper
             0.6895551             0.6650233             0.7132841
                 level
             0.9000000

confint(binom.test(713, 1034, conf.level = 0.95))

probability of success                 lower                 upper
             0.6895551             0.6603601             0.7176665
                 level
             0.9500000

confint(binom.test(713, 1034, conf.level = 0.99))

probability of success                 lower                 upper
             0.6895551             0.6511883             0.7261507
                 level
             0.9900000
```

Sample size

Figure3.12

```
confint(binom.test(70, 100))

probability of success                 lower                 upper
             0.7000000             0.6001853             0.7875936
                 level
             0.9500000

confint(binom.test(140, 200))

probability of success                 lower                 upper
             0.7000000             0.6313501             0.7626104
                 level
             0.9500000

confint(binom.test(280, 400))

probability of success                 lower                 upper
             0.7000000             0.6524781             0.7445333
                 level
             0.9500000
```

Optional: Effect of sample proportion

Sample proportions will affect confidence intervals calculated by using accurate multipliers and the standard error of the observed sample proportion (Theory-Based Inference applet). However, the sample proportions will not affect confidence intervals found by using the exact test for proportions, `binom.test()`.

Figure3.13

```
confint(binom.test(838, 1034))
```

```
probability of success                 lower                 upper
             0.8104449             0.7852004             0.8339078
                 level
             0.9500000
```

```

```

Exploration3.4.6

```
n <- 1039
mean <- 704
sd <- 300
SE <- sd / sqrt(n)
MoE <- 2 * SE; MoE    # margin of error for 95% CI
```

```
[1] 18.61416
```

```
mean - MoE            # lower limit of 95% CI
```

```
[1] 685.3858
```

```
mean + MoE            # upper limit of 95% CI
```

```
[1] 722.6142
```

The impact of sample size

Exploration3.4.8

```
n <- 477
mean <- 704
sd <- 300
SE <- sd / sqrt(n)
MoE <- 2 * SE; MoE    # margin of error for 95% CI
```

```
[1] 27.47211
```

```
mean - MoE            # lower limit of 95% CI
```

```
[1] 676.5279
```

```
mean + MoE            # upper limit of 95% CI
```

```
[1] 731.4721
```

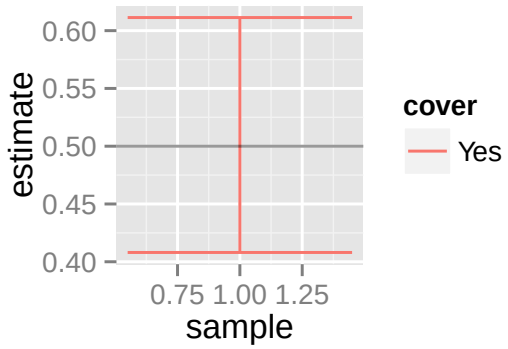
Exploration 3.4B: Reese's Pieces

Simulate 1 sample proportion and calculate the 95% confidence interval:

Exploration3.4B.4

```
sample.CI <- CIsim(100, samples = 1, rdist = rbinom, args = list(size = 1, prob = 0.5), method = binom.test,
    method.args = list(success = 1), verbose = FALSE, estimand = 0.5)
sample.CI
```

```
      lower     upper estimate cover sample
1 0.4080363 0.6113558     0.51   Yes      1
```



Simulate 100 sample proportions and calculate the 95% confidence intervals:

Exploration3.4B.5

```
sim.CI <- CIsim(100, samples = 100, rdist = rbinom, args = list(size = 1, prob = 0.5), method = binom.test,
    method.args = list(success = 1), verbose = FALSE, estimand = 0.5)
```

Proportion of intervals produced that do not contain $\pi = 0.5$:

Exploration3.4B.5b

```
prop(~cover, data = sim.CI)
```

```
    target level:  No;  other levels:  Yes
```

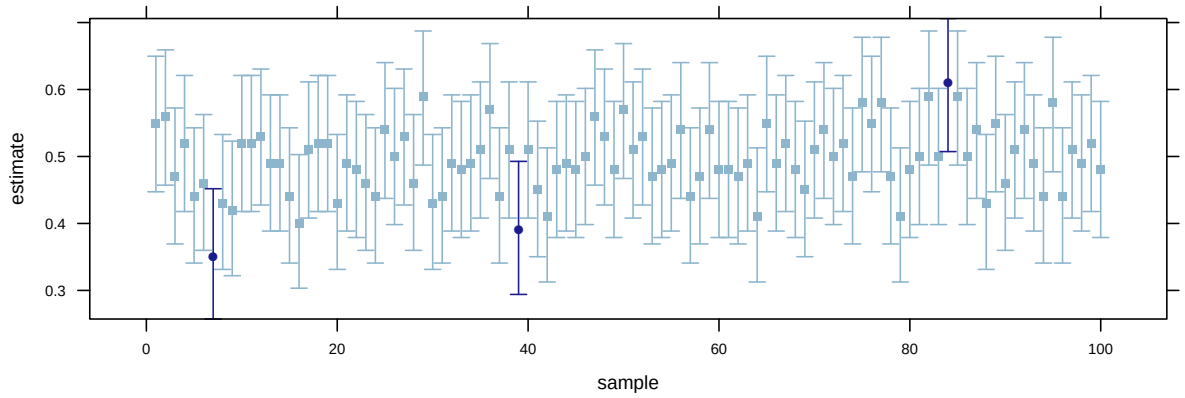
```
  No
0.03
```

Plot the 95% confidence intervals of the simulation of 100 sample proportions:

Exploration3.4B.5c

```
require(Hmisc)
xYplot(Cbind(estimate, lower, upper) ~ sample, data = sim.CI, par.settings = col.mosaic(),
    groups = cover)
```

 ©2014



Simulate 1000 sample proportions and calculate the 95% confidence intervals:

Exploration3.4B.5d

```
sim.CI2 <- CIsim(100, samples = 1000, rdist = rbinom,
                 args = list(size = 1, prob = 0.5), method = binom.test,
                 method.args = list(success = 1), verbose = FALSE,
                 estimand = 0.5)
```

Proportion of intervals produced that do not contain $\pi = 0.5$:

Exploration3.4B.5e

```
prop(~cover, data = sim.CI2)
```

```
    target level:  No;  other levels:  Yes
```

```
   No
0.039
```

Simulate 1000 sample proportions and calculate the 90% confidence intervals:

Exploration3.4B.6

```
sim.CI3 <- CIsim(100, samples = 1000, rdist = rbinom,
                 args = list(size = 1, prob = 0.5), conf.level = 0.90,
                 method = binom.test, method.args = list(success = 1),
                 verbose = FALSE, estimand = 0.5)
```

Proportion of intervals produced that do not contain $\pi = 0.5$:

Exploration3.4B.6b

```
prop(~cover, data = sim.CI3)
```

```
    target level:  No;  other levels:  Yes
```

```
   No
0.103
```

Simulate 1000 sample proportions and calculate the 90% confidence intervals (sample size = 400):

Exploration3.4B.6c

```
sim.CI4 <- CIsim(400, samples = 100, rdist = rbinom,
                 args = list(size = 1, prob = 0.5), conf.level = 0.90,
                 method = binom.test, method.args = list(success = 1),
                 verbose = FALSE, estimand = 0.5)
```

Proportion of intervals produced that do not contain $\pi = 0.5$:

Exploration3.4B.6d

```
prop(~cover, data = sim.CI4)
```

```
    target level:  No;  other levels:  Yes

  No
0.09
```

## 3.5 Cautions When Conducting Inference

1. $H_0$: $\pi = 0.3645$

   $H_a$: $\pi > 0.3645$

   Test statistic: $\hat{p} = 0.41$ (the sample proportion)

2. We simulate a world in which $\pi = 0.3645$:

   Figure3.14

   ```
   sim.obama <- do(1000) * rflip(1000, 0.3645)
   head(sim.obama, 3)
   ```

   ```
     n heads tails  prop
   1 1000   364   636 0.364
   2 1000   367   633 0.367
   3 1000   362   638 0.362
   ```

   ```
   dotPlot(~prop, data = sim.obama, groups = (prop >= 0.41), width = 0.001)
   ```

 ©2014

3. Strength of evidence:

Figure3.14b

```
favstats(~prop, data = sim.obama)

   min    Q1 median    Q3   max     mean         sd    n missing
 0.323 0.354  0.365 0.375 0.413 0.364802 0.01542396 1000       0

prop(~(prop >= 0.41), data = sim.obama)

    target level:  TRUE;  other levels:  FALSE

 TRUE
0.003
```

## Exploration 3.5A: Voting for President

Finding the 99% confidence interval using the exact test for proportions:

Exploration3.5A.3

```
confint(binom.test(1783, 2613, conf.level = 0.99))

probability of success                 lower                 upper
             0.6823574             0.6583871             0.7056569
                 level
             0.9900000
```

Another famous case of problems in Presidential election polling

Finding the 99% confidence interval using the exact test for proportions:

Exploration3.5A.9

```
confint(binom.test(1368000, 2400000, conf.level = 0.999))  # 1368000 = 2400000 * 0.57

probability of success                 lower                 upper
             0.5700000             0.5689480             0.5710515
                 level
             0.9990000
```

## Example 3.5B: Parapsychology Studies (continued)

Example3.5B

```
confint(binom.test(709, 2124, conf.level = 0.95))

probability of success                 lower                 upper
             0.3338041             0.3137548             0.3543132
                 level
             0.9500000
```

```
confint(binom.test(709, 2124, conf.level = 0.99))

probability of success                lower                upper
             0.3338041             0.3076114             0.3607496
                 level
             0.9900000
```

1. $H_0$: $\pi = 0.25$

   $H_a$: $\pi > 0.25$

   Test statistic: $\hat{p} = 0.38$ (the sample proportion of 19/50)

2. We simulate a world in which $\pi = 0.25$:

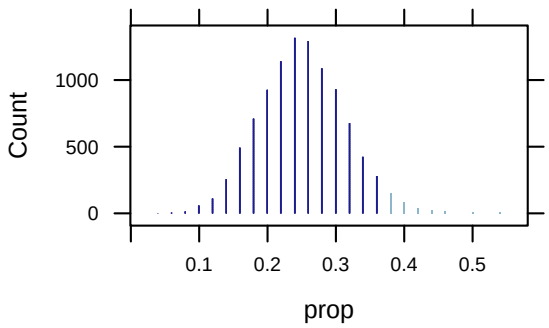
Figure3.15

```
sim.esp2 <- do(10000) * rflip(50, 0.25)
head(sim.esp2, 3)

   n heads tails prop
1 50    12    38 0.24
2 50    13    37 0.26
3 50     8    42 0.16

dotPlot(~prop, data = sim.esp2, groups = (prop >= 0.38), width = 0.01, cex = 10)
prop(~(prop >= 0.38), data = sim.esp2)

  TRUE
0.0282
```



1. $H_0$: $\pi = 1/3$

   $H_a$: $\pi > 1/3$

   Test statistic: $\hat{p} = 0.38$ (the sample proportion of 19/50)

2. We simulate a world in which $\pi = 1/3$:

Figure3.16

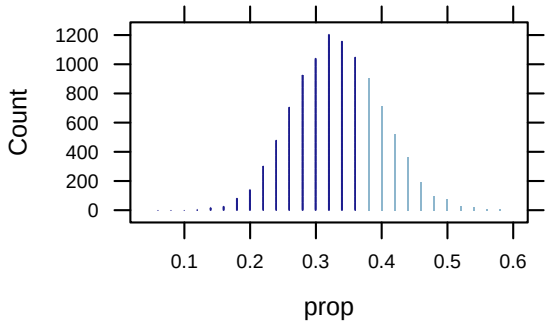
```
sim.esp3 <- do(10000) * rflip(50, 1/3)
head(sim.esp3, 3)
```

 ©2014

```
  n heads tails prop
1 50    14    36 0.28
2 50    20    30 0.40
3 50    12    38 0.24
```

```
dotPlot(~prop, data = sim.esp3, groups = (prop >= 0.38), width = 0.01, cex = 10)
prop(~(prop >= 0.38), data = sim.esp3)
```

```
 TRUE
0.287
```



1. $H_0$: $\pi = 1/2$

   $H_a$: $\pi > 1/2$

   Test statistic: $\hat{p} = 0.38$ (the sample proportion of 19/50)

2. We simulate a world in which $\pi = 1/2$:

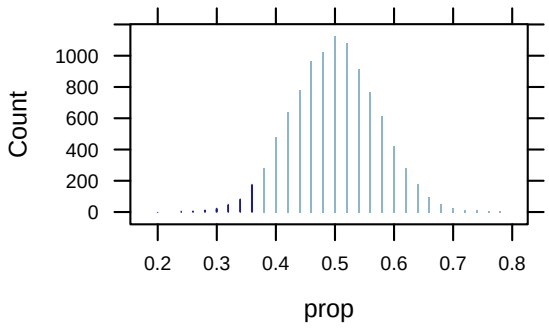
Figure3.17

```
sim.esp4 <- do(10000) * rflip(50, 1/2)
head(sim.esp4, 3)
```

```
  n heads tails prop
1 50    24    26 0.48
2 50    26    24 0.52
3 50    24    26 0.48
```

```
dotPlot(~prop, data = sim.esp4, groups = (prop >= 0.38), width = 0.01, cex = 10)
prop(~(prop >= 0.38), data = sim.esp4)
```

```
  TRUE
0.9654
```



### 3.5.1 Exploration 3.5B: Cat Households

1. $H_0$: $\pi = 1/3$
   $H_a$: $\pi < 1/3$
   Test statistic: $\hat{p} = 0.324$ (the sample proportion of 15228/47000)
2. Exact test for proportions:

Exploration3.5B.3

```
binom.test(15228, 47000, p = 1/3, conf.level = 0.999, alt = "less")
```

```
Exact binomial test (with Score CI)

data:  15228 out of 47000
number of successes = 15228, number of trials = 47000, p-value = 8.654e-06
alternative hypothesis: true probability of success is less than 0.3333333
99.9 percent confidence interval:
 0.0000000 0.3307064
sample estimates:
probability of success
                 0.324
```

```
binom.test(15228, 47000, p = 1/3, alt = "less")
```

```
Exact binomial test (with Score CI)

data:  15228 out of 47000
number of successes = 15228, number of trials = 47000, p-value = 8.654e-06
alternative hypothesis: true probability of success is less than 0.3333333
95 percent confidence interval:
 0.0000000 0.3275694
sample estimates:
probability of success
                 0.324
```

3. We simulate a world in which $\pi = 1/3$:

Exploration3.5B.9

```
sim.pets <- do(1000) * rflip(100, 1/3)
head(sim.pets, 3)
```

 ©2014

```
    n heads tails prop
1 100    29    71 0.29
2 100    33    67 0.33
3 100    31    69 0.31
```

We could use trial-and-error to determine values of the sample proportion that would produce a p-value of less than 0.05. R can quickly calculate try possible values that would result in the significance level of 0.05 but we can also have R calculate them for us.

Exploration3.5B.9b

```
cdata(0.95, prop, data = sim.pets)
```

```
      low        hi central.p
     0.25      0.43      0.95
```

1. $H_0$: $\pi = 0.30$

   $H_a$: $\pi < 0.30$

   Test statistic: $\hat{p} = 0.243$ (the sample proportion)

2. We simulate a world in which $\pi = 0.30$:

Exploration3.5B.11

```
sim.pets2 <- do(1000) * rflip(100, 0.3)
head(sim.pets2, 3)
```

```
    n heads tails prop
1 100    33    67 0.33
2 100    26    74 0.26
3 100    32    68 0.32
```

```
prop(~(prop <= 0.243), data = sim.pets2)
```

```
 TRUE
0.099
```

# 4 Causation: Can We Say What Caused the Effect?

## 4.1 Association and Confounding

### Example 4.1: Night Lights and Near-Sightedness

Often, when a dataset has only categorical variables, it may come in the form of a table and not a frame.

Here is a way to create a data frame in R.

```
NightLight1
```

```
     Darkness NightLight RoomLight
Near       18         78        41
Not       154        154        34
```

```
NightLight <- rbind(
  do(18)  *  data.frame(light = "Darkness",   nearsight = "Near"),
  do(154) *  data.frame(light = "Darkness",   nearsight = "Not"),
  do(78)  *  data.frame(light = "NightLight", nearsight = "Near"),
  do(154) *  data.frame(light = "NightLight", nearsight = "Not"),
  do(41)  *  data.frame(light = "RoomLight",  nearsight = "Near"),
  do(34)  *  data.frame(light = "RoomLight",  nearsight = "Not")
 )
```

```
head(NightLight)
```

```
     light nearsight .row .index
1 Darkness      Near    1      1
2 Darkness      Near    1      2
3 Darkness      Near    1      3
4 Darkness      Near    1      4
5 Darkness      Near    1      5
6 Darkness      Near    1      6
```

Table4.1

```
tally(nearsight ~ light, data = NightLight)
```

```
         light
nearsight Darkness NightLight RoomLight
     Near       18         78        41
     Not       154        154        34
```

```
tally(~nearsight | light, data = NightLight)
```

```
         light
nearsight Darkness NightLight RoomLight
     Near       18         78        41
     Not       154        154        34
```

```
tally(~nearsight + light, data = NightLight, margins = TRUE)
```

```
         light
nearsight Darkness NightLight RoomLight Total
    Near        18         78        41   137
    Not        154        154        34   342
    Total      172        232        75   479
```

## 4.2 Observational studies versus experiments

### Exploration 4.2: Have a Nice Trip

```
sim <- do(2) * rflip(12, 16/24)
sim
```

```
   n heads tails      prop
1 12     8     4 0.6666667
2 12     8     4 0.6666667
```

# 5 Comparing Two Proportions

## 5.1 Comparing Two Groups: Categorical Response

Example 5.1: Good and Bad Perceptions

```
head(GoodandBad, 30)
```

Table5.1

| | wording | perception |
|---|---|---|
| 1 | goodyear | positive |
| 2 | goodyear | negative |
| 3 | badyear | positive |
| 4 | goodyear | positive |
| 5 | goodyear | negative |
| 6 | badyear | positive |
| 7 | goodyear | positive |
| 8 | goodyear | positive |
| 9 | goodyear | positive |
| 10 | badyear | negative |
| 11 | goodyear | negative |
| 12 | badyear | negative |
| 13 | goodyear | positive |
| 14 | badyear | negative |
| 15 | goodyear | positive |
| 16 | goodyear | positive |
| 17 | badyear | positive |
| 18 | goodyear | positive |
| 19 | goodyear | positive |
| 20 | goodyear | positive |
| 21 | badyear | negative |
| 22 | goodyear | positive |
| 23 | badyear | negative |
| 24 | goodyear | positive |
| 25 | badyear | negative |
| 26 | goodyear | positive |
| 27 | badyear | negative |
| 28 | goodyear | positive |
| 29 | badyear | positive |
| 30 | badyear | negative |

Table5.2

```
tally(~Perception + Wording, data = GoodandBad, margins = TRUE)
```

```
Error in eval(expr, envir, enclos):  object 'Perception' not found
```

```
tally(Perception ~ Wording, data = GoodandBad)

  Death       100       357
  NoDeath     157      1027
```

```
diff(prop(patient ~ shift, data = Nurse2))  # diff in conditional prop
```

```
    target level:  Death;  other levels:  NoDeath
```

```
Death.NoGilbert
     -0.1311571
```

## 5.2 Comparing Two Properties: Simulation-Based Approach

### Example 5.2: Swimming with Dolphins

Table5.3

```
head(Dolphin)
```

```
  swimming response
1  Dolphin  Improve
2  Dolphin  Improve
3  Dolphin  Improve
4  Dolphin  Improve
5  Dolphin  Improve
6  Dolphin  Improve
```

```
tally(~Response + Swimming, data = Dolphin, margin = TRUE)
```

 ©2014

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

```
tally(Response ~ Swimming, data = Dolphin)
```

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

Figure5.2

```
diff(prop(Response ~ Swimming, data = Dolphin))
```

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

```
mosaic(Response ~ Swimming, data = Dolphin, dir = "v")
```

```
Error in eval(expr, envir, enclos):  object 'Swimming' not found
```

Figure5.4

```
mosaic(shuffle(Response) ~ Swimming, data = Dolphin, dir = "v")
```

```
Error in eval(expr, envir, enclos):  object 'Swimming' not found
```

Figure5.5

```
tally(~shuffle(Response) + Swimming, data = Dolphin, margins = TRUE)
```

```
Error in sample(x, replace = replace, prob = prob, groups = groups):  object 'Response' not found
```

```
tally(~shuffle(Response) + Swimming, data = Dolphin, margins = TRUE)
```

```
Error in sample(x, replace = replace, prob = prob, groups = groups):  object 'Response' not found
```

```
tally(~shuffle(Response) + Swimming, data = Dolphin, margins = TRUE)
```

```
Error in sample(x, replace = replace, prob = prob, groups = groups):  object 'Response' not found
```

```
diff(prop(Response ~ Swimming, data = Dolphin))
```

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

```
diff(prop(shuffle(Response) ~ Swimming, data = Dolphin))
```

```
Error in sample(x, replace = replace, prob = prob, groups = groups):  object 'Response' not found
```

1. $H_0$: $\pi_{dolphins} - \pi_{control} = 0$
   $H_a$: $\pi_{dolphins} - \pi_{control} > 0$
   Test statistic: $\hat{p}_{dolphins} - \hat{p}_{control} = 0.4667$ (the difference in the conditional sample proportions)

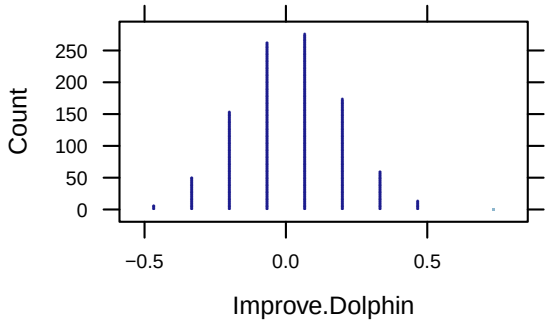
2. We simulate a world in which $\pi_{dolphins} - \pi_{control} = 0$:

```
sim.dol <- do(1000) * diff(prop(shuffle(Response) ~ Swimming, data = Dolphin))
head(sim.dol, 3)
```

Figure5.6

```
  Improve.Dolphin
1          0.4667
2          0.3333
3         -0.2000
```

```
dotPlot(~Improve.Dolphin, data = sim.dol, groups = (Improve.Dolphin >= 0.4667), width = 1/15,
    cex = 5)
```



3. Strength of evidence:

```
favstats(~Improve.Dolphin, data = sim.dol)
```

Figure5.6b

```
        min          Q1     median         Q3       max       mean         sd    n missing
 -0.4666667 -0.06666667 0.06666667 0.06666667 0.7333333 0.01186667 0.1812513 1000       0
```

```
prop(~(Improve.Dolphin >= 0.4667), data = sim.dol)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.001
```

Approximate test for difference in proportions:

```
prop.test(Response ~ Swimming, data = Dolphin)
```

Figure5.6c

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

### Estimation

Determining a 95% confidence interval using the 2SD Method and simulated standard deviation of the null distribution:

 ©2014

Example5.2

```
# given difference in sample proportions
diff <- diff(prop(Response ~ Swimming, data = Dolphin))
```

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

```
# simulated standard deviation
sd <- sd(~Improve.Dolphin, data = sim.dol)
# margin of error for 95% CI
MoE <- 2 * sd
MoE
```

```
[1] 0.3625026
```

```
# lower limit of 95% CI
diff - MoE
```

```
Error in diff - MoE: non-numeric argument to binary operator
```

```
# upper limit of 95% CI
diff + MoE
```

```
Error in diff + MoE: non-numeric argument to binary operator
```

Determining a 95% confidence interval using the approximate test for proportions:

Example5.2b

```
confint(prop.test(Response ~ Swimming, data = Dolphin))
```

```
Error in eval(expr, envir, enclos):  object 'Response' not found
```

### Follow-up Analysis

Figure5.7

```
Dolphin2 <- rbind(
  do(8)  *  data.frame(Response = "Improve",    Swimming = "Control"),
  do(5)  *  data.frame(Response = "Improve",    Swimming = "Dolphin"),
  do(7)  *  data.frame(Response = "NotImprove", Swimming = "Control"),
  do(10) *  data.frame(Response = "NotImprove", Swimming = "Dolphin")
   )
```

Figure5.7b

```
tally(~Response + Swimming, data = Dolphin2, margin = TRUE)
```

```
           Swimming
Response     Control Dolphin Total
  Improve          8       5    13
  NotImprove       7      10    17
  Total           15      15    30
```

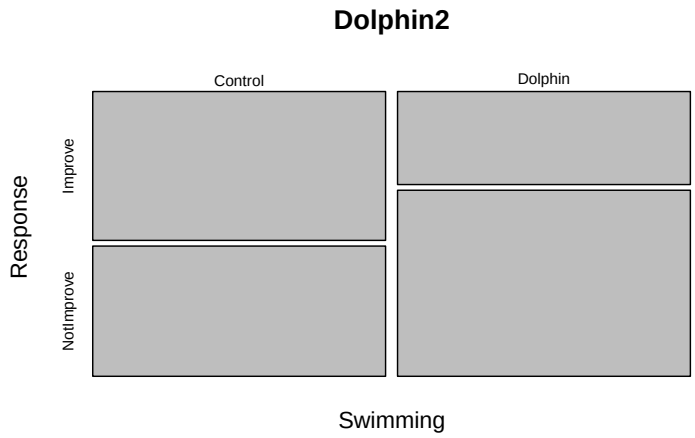
```
diff(prop(Response ~ Swimming, data = Dolphin2))
```

```
    target level:  Improve;  other levels:  NotImprove
```

```
Improve.Dolphin
           -0.2
```

Figure5.7c

```
mosaicplot(Swimming ~ Response, data = Dolphin2)
```



1. $H_0$: $\pi_{dolphins} - \pi_{control} = 0$

   $H_a$: $\pi_{dolphins} - \pi_{control} > 0$

   Test statistic: $\hat{p}_{dolphins} - \hat{p}_{control} = 0.20$ (the difference in the conditional sample proportions)

2. We simulate a world in which $\pi_{dolphins} - \pi_{control} = 0$:

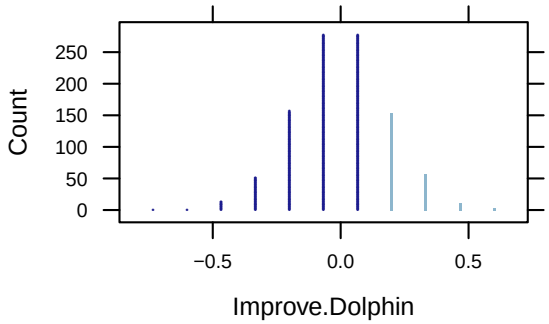
Figure5.7d

```
sim.dol2 <- do(1000) * diff(prop(shuffle(Response) ~ Swimming, data = Dolphin2))
head(sim.dol2, 3)
```

```
  Improve.Dolphin
1         0.06667
2        -0.20000
3        -0.06667
```

```
dotPlot(~Improve.Dolphin, data = sim.dol2, groups = (Improve.Dolphin >=0.20),
        width = 1/15, cex = 5)
```

 ©2014



3. Strength of evidence:

## Estimation

Exploration5.2.24

```
sd <- sd(~Yawn.Seeded, data = sim.yawn2)
sd
```

```

[1] 0.1403745
```

Determining a 95% confidence interval using the 2SD Method and simulated standard deviation of the null distribution:

Exploration5.2.24b

```

# given difference in sample proportions
diff <- diff(prop(Response ~ YawnSeed, level = "Yawn", data = Yawning2))
```

```
    target level:  Yawn;  other levels:  NoYawn
```

```
# previously found simulated standard deviation
sd
```

```

[1] 0.1403745
```

```
# margin of error for 95% CI
MoE <- 2 * sd
MoE

[1] 0.2807491

# lower limit of 95% CI
diff - MoE

Yawn.Seeded
 -0.2366314

# upper limit of 95% CI
diff + MoE

Yawn.Seeded
  0.3248667
```

Determining a 95% confidence interval using the approximate test for proportions:

Exploration5.2.24c

```
confint(prop.test(Response ~ YawnSeed, data = Yawning2))

    prop 1     prop 2      lower      upper      level
 0.7500000  0.7058824 -0.2616754  0.3499107  0.9500000
```

# 7 Paired Data: One Quantitative Variable

## 7.1 Paired Designs

## 7.2 Simulation-Based Approach for Analyzing Paired Data

### Example 7.2: Rounding First Base (continued)

Let's begin by creating a data frame that organizes this data differently. We'll call the new data frame `FirstBase2`.

Example7.2

```
require(tidyr)
FirstBase2 <- FirstBase %>% gather(key = angle, value = time, narrow, wide)
sample(FirstBase2, 5)
```

```
    angle time orig.ids
3  narrow 5.60        3
8  narrow 5.50        8
40   wide 5.55       40
43   wide 5.55       43
23   wide 5.55       23
```

Table7.1

```
head(FirstBase, 10)
```

```
   narrow wide
1    5.50 5.55
2    5.70 5.75
3    5.60 5.50
4    5.50 5.40
5    5.85 5.70
6    5.55 5.60
7    5.40 5.35
8    5.50 5.35
9    5.15 5.00
10   5.80 5.70
```

Figure7.3

```
dotPlot(~narrow, data = FirstBase, nint = 40, cex = 0.2, xlim = c(4.5, 6.5))
dotPlot(~wide, data = FirstBase, nint = 40, cex = 0.1, xlim = c(4.5, 6.5))
densityplot(~time, groups = angle, data = FirstBase2)
```

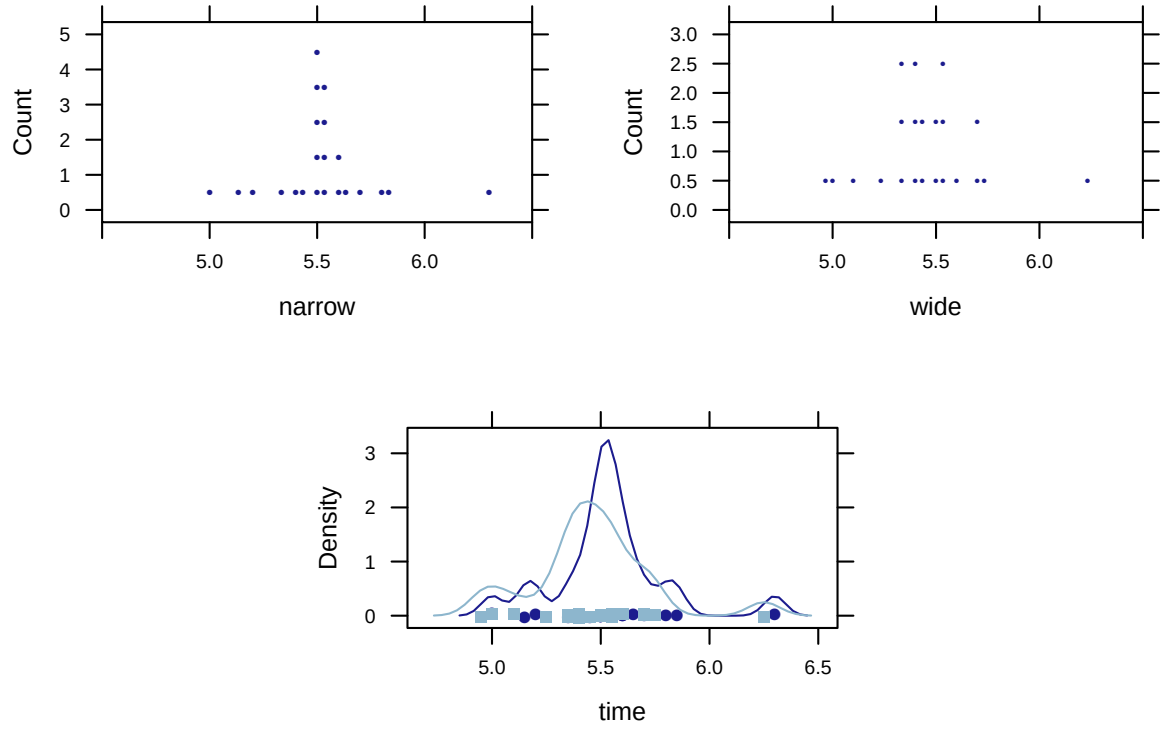

Table7.2

```
favstats(~(narrow - wide), data = FirstBase)
```

```
  min   Q1 median     Q3 max  mean         sd  n missing
 -0.1 0.05    0.1 0.1375 0.2 0.075 0.08830413 22       0
```

Figure7.4

```
dotPlot(~(narrow - wide), data = FirstBase)
```

©2014

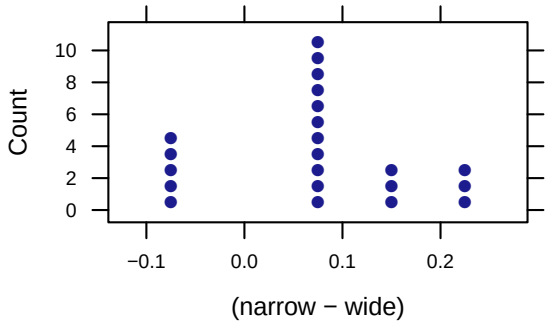

Table7.3

```
Swap.Base <- swap(FirstBase, c("narrow", "wide"))
Swap.Base
```

```
   narrow wide
1    5.50 5.55
2    5.70 5.75
3    5.50 5.60
4    5.50 5.40
5    5.85 5.70
6    5.55 5.60
7    5.40 5.35
8    5.50 5.35
9    5.15 5.00
10   5.80 5.70
11   5.20 5.10
12   5.45 5.55
13   5.45 5.35
14   4.95 5.00
15   5.40 5.50
16   5.55 5.50
17   5.35 5.55
18   5.50 5.55
19   5.25 5.45
20   5.40 5.60
21   5.65 5.55
22   6.30 6.25
```

```
mean(~(narrow - wide), data = Swap.Base)
```

```

```
prop(~(result <= -0.384 | result >= 0.384), data = sim.auction)
```

```
    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

4. t-test for paired samples (theory-based approach):

Exploration7.3.7

```
t.test(Auction$dutch, Auction$FP, paired = TRUE)

Paired t-test

data:  Auction$dutch and Auction$FP
t = 5.3284, df = 87, p-value = 7.692e-07
alternative hypothesis: true difference in means is not equal to 0
95 percent confidence interval:
 0.2404602 0.5265853
sample estimates:
mean of the differences
              0.3835227

t.test(~(dutch - FP), data = Auction)

One Sample t-test

data:  data$(dutch - FP)
t = 5.3284, df = 87, p-value = 7.692e-07
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
 0.2404602 0.5265853
sample estimates:
mean of x
0.3835227
```

95% confidence interval using the t-test:

Exploration7.3.8

```
confint(t.test(Auction$dutch, Auction$FP, paired = TRUE))

mean of the differences                lower                upper
              0.3835227            0.2404602            0.5265853
                  level
              0.9500000
```

# 8 Comparing More Than Two Proportions

## 8.1 Simulation-Based Approach to Compare Multiple Proportions

### Example 8.1: Coming to a Stop

Table8.1

```
require(vcd)
sample(Stop, 5)
```

```
    position stop orig.ids
100   single  yes      100
124   single  yes      124
144   single  yes      144
102   single  yes      102
154   single   no      154
```

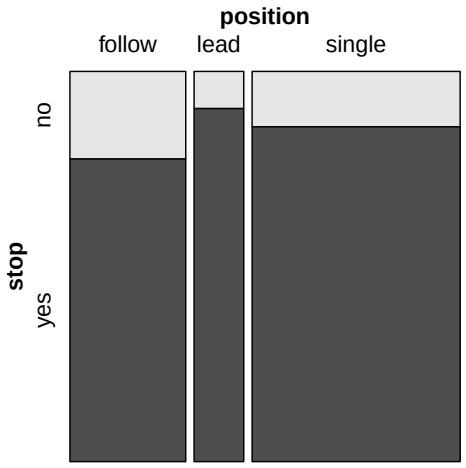
```
tally(~stop + position, data = Stop, margins = TRUE)
```

```
       position
stop    follow lead single Total
  no        22    4     25    51
  yes       76   38    151   265
  Total     98   42    176   316
```

```
tally(stop ~ position, data = Stop)
```

```
     position
stop  follow lead single
  no      22    4     25
  yes     76   38    151
```

```
mosaic(stop ~ position, data = Stop, direction = "v")
```



Mean Absolute Difference (MAD)

We can input the proportions to compute MAD:

Figure8.1

```
MAD(prop(stop ~ position, data = Stop))
```

```
    target level:  no;  other levels:  yes
```

```
[1] 0.0861678
```

Then we can shuffle the response variable:

Figure8.2

```
MAD(prop(shuffle(stop) ~ position, data = Stop))
```

```
    target level:  no;  other levels:  yes
```

```
[1] 0.03834261
```

1. $H_0$: $\pi_{Single} = \pi_{Lead} = \pi_{Follow}$
   $H_a$: At least one of the three long-run probabilities is different from the others
   Test statistic: $MAD = 0.086$ (the absolute mean difference)
2. We simulate a world in which $MAD = 0$ :

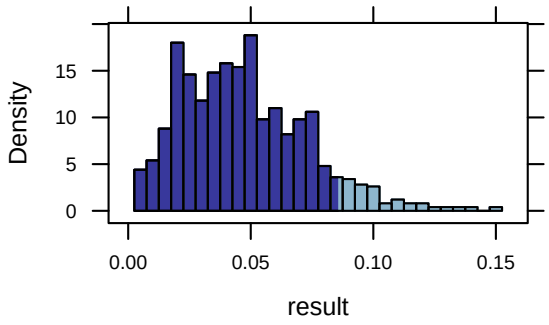
Figure8.3

```
sim.stop <- do(1000) * MAD(prop(shuffle(stop) ~ position, data = Stop, quiet = TRUE))
head(sim.stop, 3)
```

 ©2014

```
      result
1 0.07482993
2 0.02494331
3 0.06150794
```

```
histogram(~result, data = sim.stop, width = 0.005, groups = (result >= 0.086))
```



3. Strength of evidence:

Figure8.3b

```
favstats(~result, data = sim.stop)
```

```
         min         Q1     median         Q3      max       mean         sd    n missing
 0.005050505 0.02721088 0.04437229 0.06349206 0.150974 0.04716981 0.02569343 1000       0
```

```
prop(~(result >= 0.086), data = sim.stop)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.077
```

## Exploration 8.1: Recruiting Organ Donors

Exploration8.1.1

```
head(OrganDonor)
```

```
  default choice
1  opt-in  donor
2  opt-in  donor
3  opt-in  donor
4  opt-in  donor
5  opt-in  donor
6  opt-in  donor
```

Exploration8.1.5

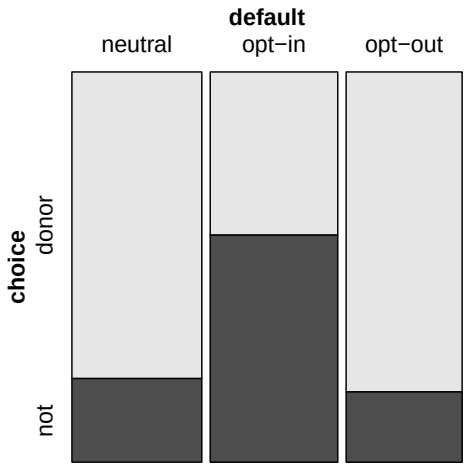
```
tally(~choice + default, data = OrganDonor)
```

```
       default
choice  neutral opt-in opt-out
  donor      44     23      41
  not        12     32       9
```

```
tally(choice ~ default, data = OrganDonor)
```

```
       default
choice  neutral opt-in opt-out
  donor      44     23      41
  not        12     32       9
```

```
mosaic(choice ~ default, data = OrganDonor, direction = "v")
```



Exploration8.1.9

```
MAD(prop(choice ~ default, data = OrganDonor))
```

```
    target level:  donor;  other levels:  not
```

```
[1] 0.2678788
```

1. $H_0$: $\pi_{opt-in} = \pi_{opt-out} = \pi_{neutral}$
   $H_a$: At least one of the three long-run probabilities is different from the others
   Test statistic: $MAD = 0.268$ (the absolute mean difference)
2. We simulate a world in which $MAD = 0$:

Exploration8.1.11

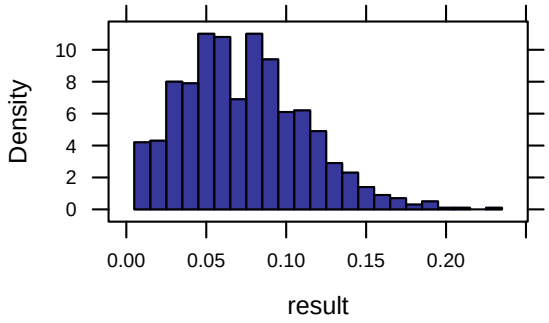
```
sim.donor <- do(1000) * MAD(prop(shuffle(choice) ~ default, data = OrganDonor, quiet = TRUE))
head(sim.donor, 3)
```

```
      result
```

 ©2014

```
1 0.08714286
2 0.03030303
3 0.04952381
```

```
histogram(~result, data = sim.donor, width = 0.01, groups = (result >= 0.268))
```



3. Strength of evidence:

Exploration8.1.12

```
favstats(~result, data = sim.donor)
```

```
       min         Q1     median         Q3       max       mean         sd    n missing
 0.01238095 0.04606061 0.06909091 0.09858225 0.2254545 0.07372848 0.03775873 1000       0
```

```
prop(~(result >= 0.086), data = sim.stop)
```

```
    target level:  TRUE;  other levels:  FALSE

 TRUE
0.077
```

## 8.2 Theory-Based Approach to Compare Multiple Proportions

### Example 8.2: Sham Acupuncture

Table8.2

```
sample(Acupuncture, 5)
```

```
     acupuncture improvement orig.ids
564         Real         Not      564

     Total   388  387  387  1162
```

```
tally(improvement ~ acupuncture, data = Acupuncture)
```

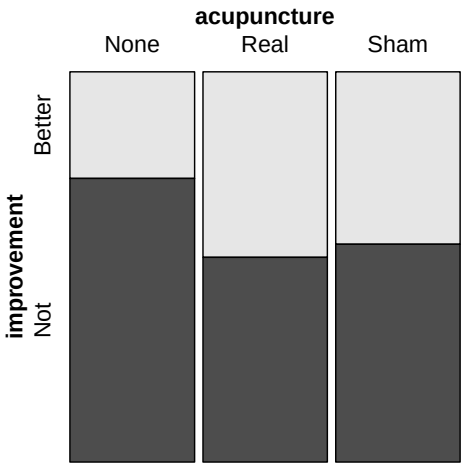
```
           acupuncture
improvement None Real Sham
     Better  106  184  171
     Not     282  203  216
```

Figure8.4

```
mosaic(improvement ~ acupuncture, data = Acupuncture, direction = "v")
MAD(prop(improvement ~ acupuncture, data = Acupuncture))
```

```
    target level:  Better;  other levels:  Not
```

```
[1] 0.1348375
```



1. $H_0$: $\pi_{real} = \pi_{sham} = \pi_{none}$
   $H_a$: At least one of the three long-run probabilities is different from the others
   Test statistic: $MAD = 0.135$ (the absolute mean difference)
2. We simulate a world in which $MAD = 0$:

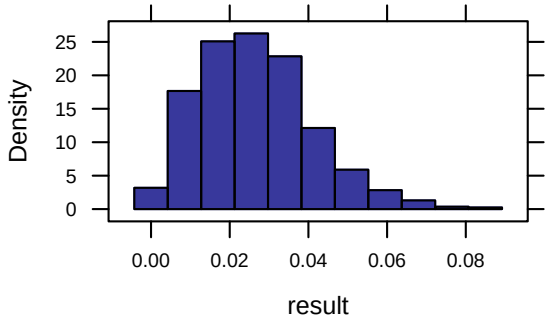
Figure8.5

```
sim.acu <- do(1000) * MAD(prop(shuffle(improvement) ~ acupuncture, data = Acupuncture, quiet = TRUE))
head(sim.acu, 3)
```

```
       result
1 0.008613264
2 0.014442757
3 0.006890612
```

©2014

```
histogram(~result, data = sim.acu, groups = (result >= 0.135))
```



3. Strength of evidence:

Figure8.5b

```
favstats(~result, data = sim.acu)

         min         Q1     median         Q3        max       mean         sd    n
 0.001722653 0.01550388 0.02511832 0.03544425 0.08668318 0.02664274 0.01440881 1000
 missing
       0

prop(~(result >= 0.135), data = sim.acu)

    target level:  TRUE;  other levels:  FALSE

TRUE
   0
```

Theory-based approach: The chi-square test

For the chi-square test, data must be tabulated.

Figure8.7

```
acu.table <- tally(~improvement + acupuncture, data = Acupuncture)
acu.table

           acupuncture
improvement None Real Sham
     Better  106  184  171
     Not     282  203  216

chisq.test(acu.table)

# 10 Two Quantitative Variables

## 10.1 Summarizing the Relationship Between Two Quantitative Variables Using the Correlation Coefficient

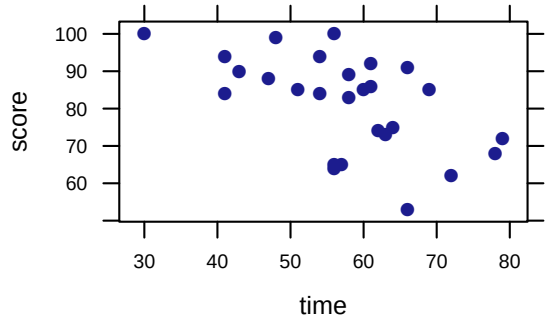
### Example 10.1: Exam Times and Exam Scores

Exploring the Data: Graphical Summary

Figure 10.1 plots data that have been modified to exclude 3 observations, so we will take the subset of ExamTimesScores.

Figure10.1

```
scores <- subset(ExamTimesScores, time < 90)
xyplot(score ~ time, data = scores)
```



Exploring the Data: Numerical Summary

Example10.1

```
cor(score ~ time, data = scores)
```

```

## 10.3 Least Squares Regression

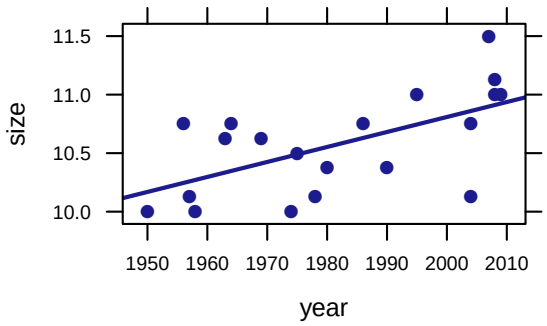
R provides the simple command `lm()` to find the least squares line.

Figure10.7

```
xyplot(size ~ year, data = PlateSize, type = c("p", "r"))
lm(size ~ year, data = PlateSize)
```

```
Call:
lm(formula = size ~ year, data = PlateSize)

Coefficients:
(Intercept)         year
   -14.8003       0.0128
```



Note that `type = c("p", "r")` adds the least squares regression line to the scatterplot.

For just the coeffients:

Figure10.7b

```
coef(lm(size ~ year, data = PlateSize))

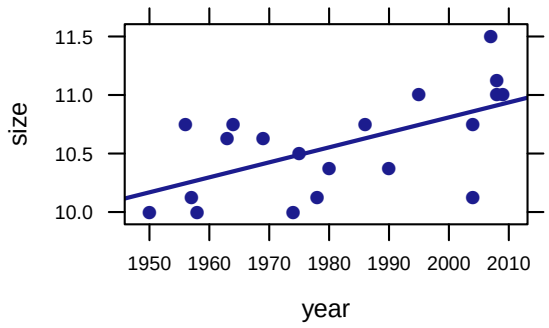
 (Intercept)         year
-14.80033212   0.01280451
```

Figure10.8

```
xyplot(size ~ year, data = PlateSize, type = c("p", "r"))
resid(lm(size ~ year, data = PlateSize))  # residuals for each point

          1           2           3           4           5           6           7
-0.16845690  0.50471606 -0.13308845 -0.27089295  0.29008451  0.40228000  0.21325747
          8           9          10          11          12          13          14
-0.47576507  0.01143042 -0.40198310 -0.17759211  0.12058084 -0.30563718  0.25534028
         15          16          17          18          19          20
-0.10990028 -0.73490028  0.60168619  0.08888169  0.21388169  0.07607718
```

 ©2014



For more information, including the **coefficient of determination,** use the `summary()` function on the linear model.

Figure10.8b

```
summary(lm(size ~ year, data = PlateSize))
```

```

Call:
lm(formula = size ~ year, data = PlateSize)

Residuals:
     Min       1Q   Median       3Q      Max
-0.73490 -0.20092  0.04375  0.22425  0.60169

Coefficients:
             Estimate Std. Error t value Pr(>|t|)
(Intercept) -14.800332   7.897098  -1.874  0.07724 .

Residual standard error: 0.3521 on 18 degrees of freedom
Multiple R-squared:  0.3645,Adjusted R-squared:  0.3292
F-statistic: 10.33 on 1 and 18 DF,  p-value: 0.004818
```

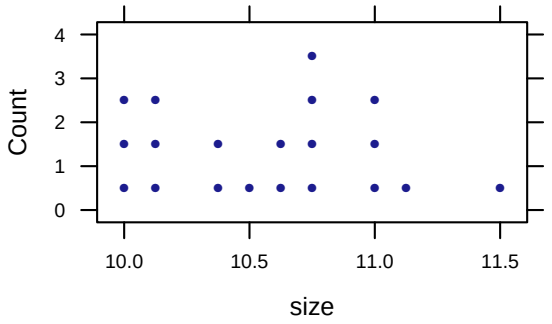
```
rsquared(lm(size ~ year, data = PlateSize))  # just the r-squared
```

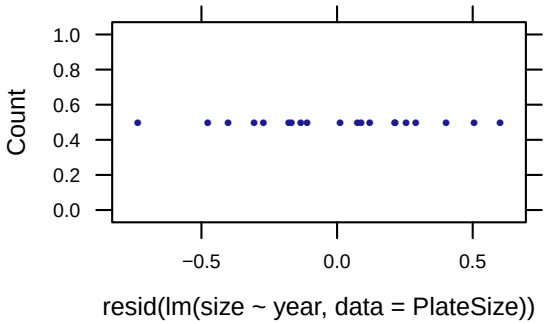
```

[1] 0.3645411
```

Figure10.9

```
dotPlot(~size, data = PlateSize, width = 0.005, cex = 0.25)
dotPlot(~resid(lm(size ~ year, data = PlateSize)), width = 0.001, cex = 0.05)
```





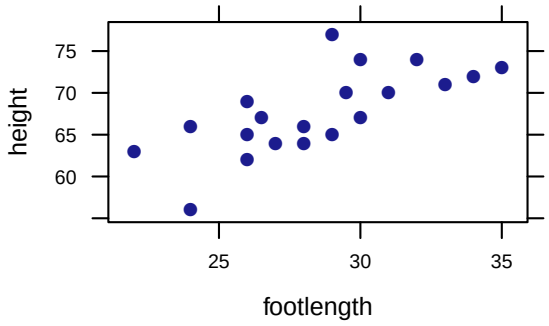
Exploration10.3.1

```
head(FootHeight, 3)
```

```
  footlength height
1         32     74
2         24     66
3         29     77
```

Exploration10.3.2

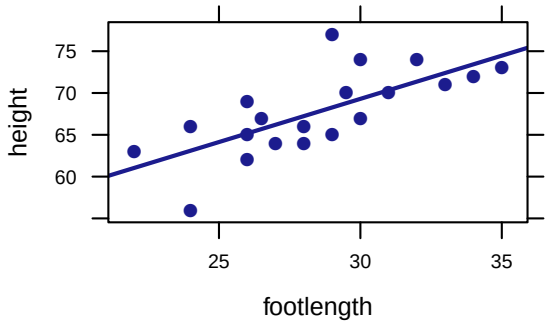
```
xyplot(height ~ footlength, data = FootHeight)
```



Exploration10.3.4

```
xyplot(height ~ footlength, data = FootHeight, type = c("p", "r"))
```

©2014



Exploration10.3.6

```
# sum of the absolute values of the residuals of the linear model
sum(abs(resid(lm(height ~ footlength, data = FootHeight))))
```

```
[1] 54.59867
```

Exploration10.3.7

```
# sum of the squared residuals
deviance(lm(height ~ footlength, data = FootHeight))
```

```
[1] 235.0006
```

Exploration10.3.8

```
coef(lm(height ~ footlength, data = FootHeight))
```

```
(Intercept)  footlength
  38.302106    1.033259
```

To make predictions, we can make a function out of the linear model by using the `makeFun()` function.

Exploration10.3.9

```
# assigning function of the linear model the name fh
fh <- makeFun(lm(height ~ footlength, data = FootHeight))
fh(footlength = 28)  # predicted height for foot length 28
```

```

## 10.4 Inference for Regression Slope: Simulation-Based Approach

### Example 10.4: Do students who spend more time in non-academic activities, tend to have lower GPAs?

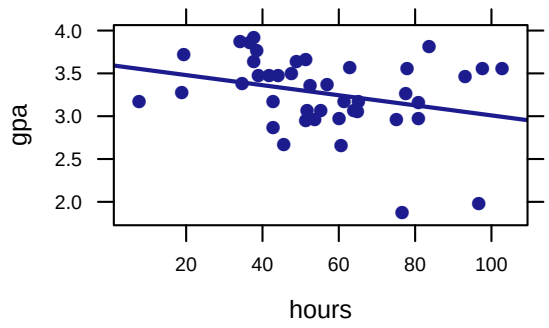
Figure10.10

```
xyplot(gpa ~ hours, data = GPA, type = c("p", "r"))
cor(gpa ~ hours, data = GPA)
```

```
[1] -0.290021
```

```
coef(lm(gpa ~ hours, data = GPA))
```

```
 (Intercept)        hours
3.597690950 -0.005883873
```



1. $H_0$: $slope = 0$

   $H_a$: $slope < 0$

   Test statistic: $slope = -0.00588$ (the sample slope coefficient)

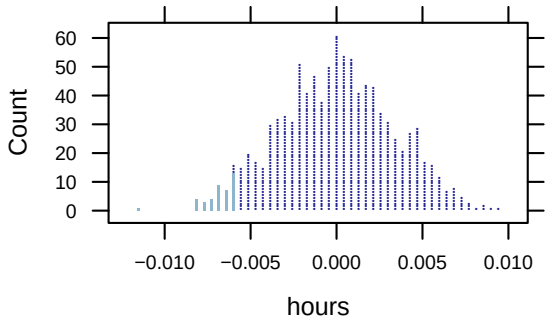
2. We simulate a world in which $slope = 0$:

Figure10.11

```
sim.gpa <- do(1000) * coef(lm(shuffle(gpa) ~ hours, data = GPA))
head(sim.gpa, 3)
```

```
  Intercept      hours
1     3.338 -0.0012894
2     3.296 -0.0005489
3     3.212  0.0009405
```

```
dotPlot(~hours, data = sim.gpa, n = 50, groups = (hours <= -0.00588))
```



3. Strength of evidence:

Figure10.11b

```
favstats(~hours, data = sim.gpa)
```

```
        min          Q1      median          Q3         max         mean          sd
